APPLICATION OF
"RULES FOR THE CLASSIFICATION OF FIXED OFFSHORE STRUCTURES"

1. Unless expressly specified otherwise, the requirements in the Rules apply to Fixed Offshore Structures for which contracts for construction are signed on or after 1 July 2014.
2. The amendments to the Rules for 2013 edition and their effective date are as follows;

Effective Date 1 July 2014

CHAPTER 1 GENERAL
Section 1 General
- 101. 1 and 2 have been amended.

CHAPTER 2 CLASSIFICATION AND SURVEYS
Section 2 Classification
- 201. (1) has been amended.

CHAPTER 4 DESIGN OF STRUCTURES
Section 1 Definitions and Design Documentation
- 104. 4 has been amended.
Section 4 General Design Requirements
- 404. has been amended.

CHAPTER 1 GENERAL

Section 1 General

101. Application

1. These Rules apply to design, construction, installation and survey for Fixed Offshore Structures classed with the Society or intended to be classed under the Society. Fixed Offshore Structures (hereafter referred to as "structure" in these Rules) as used herein means structure supported by and fixed to the sea floor of specific site of the installation.

2. For structures fixed to the sea floor with different type from those specified in this Rules, the design, fabrication, installation and examination are to be in accordance with the discretion of the Society.

3. For floating offshore production units which are provided with facilities processing, storing and/or offloading crude oil and gas produced from subsea well, Guidance for Floating Offshore Production Units is to be applied.

102. General

1. The design is to be based on foundation and long term environmental conditions at a particular installation site where it is intended to remain.

2. The sea floor attachment afforded to the platform may be obtained by pilings, direct bearing, mooring lines, anchors, etc.

3. The site condition reports are to be submitted. Specific data for an offshore structure employed by the designer meets the appropriate requirements of the Rules. The data are to include the following. However, where appropriate, data established for a previous installation in the vicinity of the installation proposed for classification may be utilized if acceptable in the opinion of the Society.
   (1) Environmental conditions of waves, winds, currents, tides, water depth, air and sea temperatures and ice
   (2) Seabed topography, stability, and pertinent geotechnical data
   (3) Seismic conditions

103. Equivalency

Alternative offshore construction, transportation, offloading, installations or offshore structure, equipment arrangement and scantlings will be accepted by the Society, provided that the Society is satisfied that such construction, equipment, arrangement and scantlings are equivalent to those required in this Rules.
CHAPTER 2  CLASSIFICATION AND SURVEYS

Section 1  General

101. General

1. The classification and surveys of the structures intended to be classed with the Society or classed with the Society are to be in accordance with the requirements specified in this Chapter.

2. In the case of items not specified in this Chapter, the requirements specified in Pt 1 of Rules for the Classification of Steel Ships are to be applied.

Section 2  Classification

201. Classification

Structures built and surveyed for the classification in accordance with this Rules or in accordance with requirements deemed to be equivalent to this Rules by the Society will be assigned a class and registered in the Register of Ships.

202. Class notations

The class will be distinguished by the class notations and the class notations assigned to the structures classed with the Society are to be in accordance with the requirements specified in Pt 1, Ch 1, 201. of Rules for the Classification of Steel Ships. However, "Fixed Offshore Structure" shall be assigned as a ship type notation and the following notations shall be assigned as special feature notations.

(A) Jacket
(B) GBS
(C) Compliant Tower
(D) Articulated Tower
(E) Special feature notations according to other types of the structure

(2) The following special feature notations shall be assigned according to a purpose of the structure.

(A) Drilling
(B) Production
(C) Special feature notations according to other purposes of the structure

203. Maintenance of classification

1. Structures classed with the Society are to be subjected to the surveys to maintain the classification and are to be maintained in good condition in accordance with the requirements specified in this Chapter.

2. Plans and particulars of any proposed alterations to the approved scantlings or arrangements of hull, machinery or equipment are to be submitted for approval by the Society before the work is commenced and such alterations are to be surveyed by the Surveyor of the Society.

204. Classification Survey during Construction

1. General

At the Classification Survey during Construction, the hull, machinery and equipment are to be examined in detail in order to ascertain that they meet the relevant requirements of this Rules.
2. Submission of plans and documents

For a structure requiring Classification Survey during Construction, the plans and documents showing the details of the construction, scantlings, materials and particulars of the structure are to be submitted in triplicate and approved before the work is commenced. The same applies also to the cases of any subsequent modifications to the approved drawings or documents.

3. Presence of Surveyors

(1) At the Classification Survey during Construction, the presence of the Surveyor is required at the following stages of the work in relation to hull and equipment.

(A) When the tests of the materials specified in Pt 2, Ch 1 of Rules for the Classification of Steel Ships and the equipment specified in Pt 4 of Rules for the Classification of Steel Ships are carried out.

(B) When the tests of welding specified in Pt 2, Ch 2 of Rules for the Classification of Steel Ships are carried out.

(C) When designated by the Society during shop work or sub-assembly.

(D) When each block is assembled and erected.

(E) When each part of the hull is completed.

(F) When structural tests, leak test, hose tests and non-destructive tests are carried out.

(G) When performance tests are carried out on closing appliances of openings, mooring equipment, cargo handling appliances, fire detection systems, etc.

(H) When each part of the fire protection construction is completed.

(I) When measurement of principal dimensions, hull deflection, etc. are carried out.

(J) When the onboard tests are carried out.

(K) When deemed necessary by the Society.

(2) At the Classification Survey during Construction, the presence of the Surveyor is required at the following stages of the work in relation to machinery.

(A) When the tests of materials of main parts of machinery specified in Pt 2 of Rules for the Classification of Steel Ships are carried out.

(B) Main parts of machinery

(a) When the tests specified in either Pt 5 or Pt 6 of Rules for the Classification of Steel Ships according to the kind of machinery are carried out.

(b) When the materials are assembled for construction of the parts and the parts are assembled for installation on board.

(c) When machining of the main parts is finished and, if necessary, at appropriate stages during machining.

(d) In case of welded construction, before welding is commenced and when it is completed.

(e) When the shop trials are carried out.

(C) When main parts of machinery are installed on board.

(D) When performance tests/onboard tests are carried out on measurement instruments, remote control devices of closing appliances, remote control devices for machinery and gears, automatic control devices, fire extinguishing equipments, piping, etc.

(E) When the sea trials are carried out.

(F) When deemed necessary by the Society.

(3) For structures requiring the mooring system when that system is installed on the structure.

4. Tests

At the Classification Survey during Construction, hydrostatic tests, leak tests, hose tests and performance tests, etc are to be carried out in accordance with the relevant requirements of this Rules.

5. Steel structures

(1) Application

The requirements of this paragraph are to apply to steel structures.

(2) Materials

The materials are to be in accordance with Ch 3, Sec 1.

(3) Welder Qualification, Welding Procedure Specification and Weld Inspection

Welder Qualification, Welding Procedure Specification and Weld Inspection are to be in accordance with Ch 3, Sec 2.
(4) Tolerances and Alignments
The overall structural tolerances, forming tolerances, and local alignment tolerances are to be commensurate with those considered in developing the structural design. Inspections are to be carried out to ensure that the dimensional tolerance criteria are being met. Particular attention is to be paid to the out-of-roundness of members for which buckling is an anticipated mode of failure.

(5) Corrosion Control System
The details of any corrosion control system employed for the structure are to be submitted for review. Installation and testing of the corrosion control system are to be carried out to the satisfaction of the attending Surveyor in accordance with the approved plans.

(6) Tightness and Hydrostatic Testing Procedures
Compartments which are designed to be permanently watertight or to be maintained watertight during installation are to be tested by a procedure approved by the attending Surveyor.

(7) Nondestructive Testing
(A) Nondestructive Testing is to be in accordance with Ch 3, Sec 2.
(B) All nondestructive testing records are to be reviewed and approved by the attending Surveyor.
(C) Additional nondestructive testing may be requested if deemed necessary by the attending Surveyor.

(8) Installation of Structure
(A) Upon completion of fabrication and when the structure is to be loaded and transported to site for installation, the load-out, tie-down and installation are to be surveyed by the attending Surveyor.
Where the structure is fabricated inland, the supporting method the structure while fabricated and storing method of the welding consumables are to be satisfied by attending Surveyor. The Surveyor is to verify the following activities, as applicable to the planned structure, to ascertain whether they have been accomplished in a manner conforming to the approved procedures.
(a) Load-out
(b) Tie-down
(c) Positioning
(d) Installation
(e) Final field erection and leveling
(B) Significant deviations from approved plans and procedures or any incidents may require re-submittal of supporting documentation to provide an assessment of the significance of deviation and any necessary remedial actions to be taken.
(C) To ensure that over stressing of the structure during transportation has not occurred, the Society is to have access to towing records to ascertain if conditions during the towing operations exceeded those employed in the analyses required in Ch 4, Sec 9.

6. Concrete structures
(1) Application
The requirements of this paragraph are to apply to concrete structures.

(2) Inspections Prior to Concreting
(A) Prior to their use in construction, the manufacture's of cement, reinforcing rods, prestressing tendons and appliances are to provide documentation of the pertinent physical properties. These data are to be made available to the attending Surveyor who will check conformity with the properties specified in the approved design.
(B) Forms and shores supporting the forms are to be inspected to insure that they are adequate in number and type, and that they are located in accordance with the approved plans.
(C) Reinforcing steel, prestressing tendons, post-tensioning ducts, anchorages and any included steel are to be checked, as appropriate to the planned structure, for size, bending, spacing, location, firmness of installation, surface condition, vent locations, proper duct coupling, and duct capping.

(3) Inspection of Batching, Mixing and Placing Concrete
(A) The production and placing of the concrete are to employ procedures which will provide a well mixed and well compacted concrete. Such procedures are also to limit segregation, loss of material, contamination, and premature initial set during all operations.
(B) Mix components of each batch of concrete are to be measured by a method specified in the quality control program. The designer is to specify the allowable variation of mix component proportions, and the constructor is to record the actual proportions of each batch.

(C) Testing during the production of concrete is to be carried out following the procedures specified in the quality control program. As a minimum, the following concrete qualities are to be measured by the Constructor.

(a) Consistency
(b) Air content
(c) Strength

(D) Field testing of aggregate gradation, cleanliness, moisture content, and unit weight is to be performed by the constructor following standards and schedules specified in the quality control program. The frequency of testing is to be determined taking into account the uniformity of the supply source, volume of concreting, and variations of atmospheric conditions. Mix water is to be tested for purity following methods and schedules specified in the quality control program.

(4) Inspection of Form Removal and Concrete Curing

(A) The structure is to have sufficient strength to bear its own weight, construction loads and the anticipated environmental loads without undue deformations before forms and form supports are removed. The schedule of form removal is to be specified in the quality control program, giving due account to the loads and the anticipated strength.

(B) Curing procedures for use on the structure are to be specified in the quality control program. When conditions at the construction site cause a deviation from these procedures, justification for these deviations is to be fully documented and included in the construction records.

(C) Where the construction procedures require the submergence of recently placed concrete, special methods for protecting the concrete from the effects of salt water are to be specified in the quality control program. Generally, concrete should not be submerged until 28 days after placing (See also Ch 4, Sec 6, 602.2).

(5) Inspection of Prestressing and Grouting

(A) A schedule indicating the sequence and anticipated elongation and stress accompanying the tensioning of tendons are to be prepared. Any failures to achieve proper tensioning are to be immediately reported to the designer to obtain guidance as to needed remedial actions.

(B) Pre- or post-tensioning loads are to be determined by measuring both tendon elongation and tendon stress. These measurements are to be compared, and should the variation of measurements exceed the specified amount, the cause of the variation is to be determined and any necessary corrective actions are to be accomplished.

(C) The grout mix is to conform to that specified in the design. The constructor is to keep records of the mix proportions and ambient conditions during grout mixing. Tests for grout viscosity, expansion and bleeding, compressive strength, and setting time are to be made by the constructor using methods and schedules specified in the quality control program. Employed procedures are to ensure that ducts are completely filed.

(D) Anchorages are to be inspected to ensure that they are located and sized as specified in the design. Anchorages are also to be inspected to assure that they will be provided with adequate cover to mitigate the effects of corrosion.

(6) Inspection of Joints

Where required, leak testing of construction joints is to be carried out using procedures specified in the quality control program. When deciding which joints are to be inspected, consideration is to be given to the hydrostatic head on the subject joint during normal operation, the consequence of a leak at the subject joint, and the ease of repair once the platform is in service.

(7) Inspection of Finished Concrete

(A) The surface of the hardened concrete is to be completely inspected for cracks, honeycombing, pop-outs, spalling and other surface imperfections. When such defects are found, their extent is to be reported to the Surveyor and to the designer for guidance on any necessary repairs.

(B) The structure is to be examined using a calibrated rebound hammer or a similar nondestructive testing device. Where the results of surface inspection, cylinder strength tests or nondestructive testing do not meet the design criteria, the designer is to be consulted regarding remedial actions which are to be taken.
(C) The completed sections of the structure are to be checked for compliance to specified design tolerances for thickness, alignment, etc., and to the extent practicable, the location of reinforcing and prestressing steel and post-tensioning ducts. Variations from the tolerance limits are to be reported to the designer for evaluation and guidance as to any necessary remedial actions.

(8) Other Inspection

(A) Upon completion of fabrication and when the structure is to be loaded and transported to site for installation, the load-out, tie-down and installation are to be surveyed by the attending Surveyor.

As applicable, at the construction site, the surveyor is to be satisfied that proper consideration is being given to the support of the structure during construction, the storage of cement and prestressing tendons in weathertight areas, the storage of admixtures and epoxies to manufacturer's specifications, and the storage of aggregates to limit segregation, contamination by deleterious substances and moisture variations within the stock pile.

(B) The Surveyor is to witness the following operations as applicable to the planned structure, to verify that they have been accomplished in a manner conforming to plans or drawings covering these operations.

(a) load-out and tie-down
(b) Towing arrangements
(c) Positioning at the site
(d) Installation
(e) Final field erection

Significant deviations from approved plans and procedures may require re-submittal of supporting documentation to provide an assessment of the significance of the deviation and the remedial action to be taken.

(C) To ensure that over-stressing of the structure during transportation has not occurred, the Society is to have access to towing records to ascertain if conditions during the towing operations exceeded those employed in the analyses required in Ch 4, Sec 9 of the Rules.

205. Classification Survey after Construction

1. General

At the Classification Survey after Construction, the examination of the hull, machinery and equipment are carried out as required for the Special Survey corresponding to the age, kind and purpose of the structures and the actual scantlings, etc. of the main parts of structures are to be measured as necessary.

2. Submission of plans and documents

At the Classification Survey after Construction, plans and documents as may be required for the Classification Survey during Construction are to be submitted. If plans and documents cannot be obtained, facilities are to be given for the Surveyor to take the necessary information from the structure.
Section 3 Surveys

301. General

1. Structures classed with the Society are to be subjected to the following surveys to maintain the classification.
   (1) Special Surveys
   (2) Annual Surveys
   (3) Continuous Surveys
   (4) Alteration Surveys
   (5) Occasional Surveys

2. Damage, failure and repair
   (1) Damage, failure, deterioration or repair to the classed structure is to be submitted by the Owner for examination by the Surveyor at first opportunity. All repairs found necessary by the Surveyor are to be carried out to Surveyor's satisfaction.
   (2) Where repairs to the structure are intended to be carried out at site, complete repair procedure including the extent of proposed repair and the need for Surveyor's attendance on site is to be submitted to and agreed upon by the Surveyor reasonably in advance.

302. Annual Surveys

1. Due range
   (1) Annual Surveys are to be carried out within three months before or after each anniversary date.
   (2) Where Surveyors are engaged in the survey of a grouping of structures of similar design and location, and where requested by the operator, special consideration will be given to the timing of Annual Surveys such that all Periodical Survey due dates can be harmonized.

2. Survey items
   (1) Each Annual Survey is to include a thorough visual examination of all above water structures. Special attention will be given to the splash zone for possible damage or deterioration from corrosion.
   (2) Additionally, where it appears that significant deterioration or damage has occurred to an installation since the last survey, a general examination, by the diver, underwater camera, submersible, or other suitable means, of the underwater structure, the sea floor, and the corrosion control system shall be carried out. Underwater examinations are to be contracted by the Operator and monitored by a Surveyor.
   (3) Any novel features incorporated in the design are to be given special attention according to procedures agreed to during review of the design. Particular attention is to be given to significant modifications or repairs made as a result of findings at the previous survey.
   (4) The Annual Survey is also to include verification that the approved design life has not been exceeded. If the end of the design life has been reached then the provisions of Ch 4, Sec 3 of the Rules are to be applied and specific requirements for maintaining the class of the structure are to be obtained from the technical office.
   (5) Assessment of the degree of marine growth shall be carried out. Should marine growth be found to be thicker than the original approved design, it is to be removed. If the Operator decides to leave the marine growth greater than what is allowed in the approved design, the Operator is to show justification that the higher hydrodynamic loading due to the additional marine growth will not affect the structural integrity of the structure.
303. Special Surveys

1. Due range

(1) Special Surveys are to be carried out at least once every five years.
(2) If a Special Survey is not completed at one time, it will be credited as of the completion date of the survey provided the due date of the Special Survey is not overdue by more than six months.
(3) Where Surveyors are engaged in the survey of a grouping of structures of similar design and location, and where requested by the operator, special consideration will be given to the timing of Special Surveys such that all Periodical Survey due dates can be harmonized.
(4) Continuous Survey
At the request of the Owner and upon the Society's approval of the proposed arrangements, a system of Continuous Surveys may be undertaken whereby the Special Survey requirements are carried out in regular rotation to complete all of the requirements of the particular Special Survey within a 5-year period. Each part(item) surveyed becomes due again for survey approximately five(5) years from the date of survey. The due parts(items) are generally to be completed each year. Continuous items that are three(3) months or more overdue at the time of Annual Survey attendance will be basis for the Annual Survey not to be credited and for non-endorsement of the Certificate of Classification. Consideration may be given by the Society to an extension to complete survey items. If any defects are found during the survey, they are to be dealt with to the satisfaction of the Surveyor.

2. Survey items

(1) The requirements of the Annual Survey are to be met during the Special Survey. Additionally, underwater inspection of selected areas of the installation is to be carried out. Also, nondestructive testing is to be carried out on representative joints of the structures and if found necessary, structural supports of conductors and risers.
(2) The extent and methods to be employed in such testing, cleaning, and inspection of the structure are to be in accordance with an approved inspection plan.
(3) The inspection plan, which is to be submitted for approval, is to cover all Special Surveys for the design life of the structure. It is to enumerate in detail the items to be surveyed, the testing and inspection procedures to be employed, and where necessary, cleaning and nondestructive testing procedures.
(4) The plan is to include sufficiently detailed drawings which can be used by the Surveyor to reference and locate the items to be surveyed.
(5) Divers carrying out structural inspections and nondestructive testing on the underwater structures are to be suitably qualified.
(6) The Special Survey is also to include monitoring of the effectiveness of the corrosion protection system. The effectiveness of the corrosion protection system is to be monitored by taking measurements of the potential voltages generated by such systems.
(7) Scour in way of platform legs, tilt and subsidence are also to be checked and witnessed by the attending Surveyor.
(8) If the end of the design life has been reached then the provisions of Ch 4, Sec 3 are to be applied and specific requirements for maintaining the class of the structure are to be obtained from the technical office.
(9) thickness measurements
(A) For the following areas, thickness measurement are required to be taken.
   (a) Structures in way of the splash zone
   (b) Suspect areas
(B) Fixed Offshore Structures consisting of converted self-elevating units will require thickness measurement where accessible in accordance with the applicable thickness measurement requirements contained in Guidance for Mobile Offshore Drilling Units.
304. Occasional Surveys

1. Reactivation Surveys

In the case of structures which have been out of service for an extended period, the requirements for surveys on reactivation are to be specially considered in each case, due regard being given to the status of surveys at the time of the commencement of the deactivation period, the length of the period, and conditions under which the structure had been maintained during that period.

2. Incomplete Surveys

When a survey is not completed, the Surveyors are to report immediately upon the work done in order that the Operator and the Head Office may be advised of the parts still to be surveyed.

3. Self-elevating Units Deployed as Fixed Offshore Structure

(1) Self-elevating Mobile Offshore Units which have been converted to site dependent platform structures will be subjected to surveys as applicable in these sections in addition to the applicable structural examinations required by Guidance for Mobile Offshore Drilling Units.

(2) Surveys are to include Annual and Special Surveys with an underwater exam in lieu of dry-docking of the above mud line sections of the legs, mats, spud cans and platform twice in each five year Special Survey period in accordance with applicable sections of Guidance for Mobile Offshore Drilling Units.

(3) Spud cans and mats which will be located below the mud line will be considered inaccessible and fatigue, structural and corrosion analyses shall be provided to justify the integrity of these inaccessible areas for the design life of the structure.

4. Survey for extension of use

(1) Existing structures to be used at the same location for an extended period of time beyond their original design life are subject to additional surveys to determine the actual condition of the structure.

(2) The extent of the survey will depend on the completeness of the existing survey documents. The Society will review and verify maintenance manual, logs and records. Any alterations, repairs or installation of equipment since installation should be included in the records.

(3) Those survey requirements in 303. for the Special Survey have to be included in the survey for extension of use.

(A) Splash zone
(B) Inspection of above water and under water structural members and welds for damages and deteriorations
(C) Examination of corrosion protection systems
(D) Measurements of marine growth
(E) Sea floor condition survey
(F) Examination of secondary structural attachments, risers and riser clamps

(4) Special attention should be given to the following critical areas.

(A) Areas of high stress
(B) Areas of low fatigue
(C) Damage incurred during installation or while in service
(D) Repairs or modifications made while in service
(E) Abnormalities found during previous surveys

(5) An inspection report of the findings is to be submitted to the Society for review and evaluation of the condition of the structure.

(6) The need for more frequent future Periodical Surveys will be determined based on the calculated remaining fatigue life and past inspection results.

5. Relocation of existing structures

(1) Existing structures that are classed at a specified location require special consideration when re-location to a new site is proposed.

(2) The Owner is to advise the Society of the proposal to change locations addressing removal, transportation and re-installation aspects of the change.

(3) Survey requirements described in 4. and 204. wherever applicable, are to be complied with in addition to an engineering analyses required to justify the integrity of the structure for the design life at the new location.
Section 4 Extension of Use and Reuse

401. Extension of Use

1. Application

This section pertains to the classification or continuance of classification of an existing structure for extension of service beyond the design life. However, if the structure is currently classed with the Society, the requirements are to be in accordance with 304. 4.

2. Extension of use

(1) The approach for the classification of an existing structure for extended service is as follows:
(A) Review original design documentation, plans, structural modification records and Survey Reports.
(B) Survey structure to establish condition of structure.
(C) Review the result of the structural analysis utilizing results of survey, original plans, specialist geotechnical and oceanographic reports and proposed modifications which affect the dead, live, environmental and earthquake loads, if applicable, on the structures.
(D) Resurvey structure utilizing results from structural analysis. Make any alterations necessary for extending the service of the structure.
(E) Review a program of continuing surveys to as-sure the continued adequacy of the structure.
(2) Items (A) and (B) are to assess, the structure to determine the possibility of continued use. If the conclusion is favorable from this assessment, structural analyses should be carried out.
(3) The in-place analysis is to follow 5 and is to be in accordance with Ch 4, 504.
(4) The fatigue life can be calculated by means of analysis as described in Ch 4, Sec 5, 506. 2 or Sec 6, 603. 4 and the remaining fatigue lives of all the structural members and joints are not to be less than twice the extended service life. The fatigue analysis may not be needed provided all of the following conditions are satisfied.
(A) The original fatigue analysis indicates that the fatigue lives of all joints are sufficient to cover the extension of use.
(B) The fatigue environmental data used in the original fatigue analysis remain valid or deemed to be more conservative.
(C) Cracks are not found during the condition survey or damaged joints and members are being repaired.
(D) Marine growth and corrosion is found to be within the allowable design limits.
(5) Surveys on a periodic basis based on Sec 3 should be undertaken to ascertain the satisfactory condition of the structure.

3. Review of structure design documents

(1) Structure design information is to be collected to allow an engineering assessment of a structure's overall structural integrity.
(2) The operator should ensure that any assumptions made are reasonable and information gathered is both accurate and representative of actual conditions at the time of the assessment. If the information can not be provided, actual measurements or testings should be carried out to establish a reasonable and conservative assumption.

4. Survey of structures

(1) Surveying an existing structure witnessed and monitored by a Surveyor is necessary to determine a base condition upon which justification of continued service can be made. Reports of previous surveys and maintenance will be reviewed, and a complete underwater inspection required to an accurate assessment of the structure's condition is obtained.
(2) The corrosion protection system is to be re-evaluated to ensure that existing anodes are capable of serving the extended design life of the structure. If found necessary by the re-evaluation, replacement of the existing anodes or additional new anodes may have to be carried out. If the increase in hydrodynamic loads due to the addition of new anodes is significant, this additional load should be taken into account in the structural analysis.
(3) The condition of protective coatings in the splash zone shall be rectified and placed in satisfactory condition.
(4) The requirements for survey are to be in accordance with 304. 4.
5. Structural analyses

(1) The structural analyses of an existing structure must incorporate the results of the structure survey. Specifically, deck loads, wastage, marine growth, scour, and any structure modifications and damages must be incorporated into the analysis model.

(2) The original fabrication materials and fit-up details must be established.

(3) The pile driving records should be made available so that the foundation can be accurately modelled.

(4) For areas where the design is controlled by earthquake or ice conditions, the analyses for such conditions should also be carried out.

(5) Possible alterations of structures to allow continued use are developed by altering the analysis model to evaluate the effect of the alterations.

(6) An analysis based on an ultimate strength method is also acceptable if the method and safety factors used are proven to be appropriate.

(7) Members and joints indicated overstressed or low in fatigue life may be improved by reducing deck load and removing unused structures such as conductors, conductor guides framing, and boat landing. The results of these load reduction on the structure should be evaluated to determine whether the repairs/alterations is needed.

6. Repairs and reinspection

(1) A second survey may be necessary to inspect areas where the analysis results indicate as being the more highly stressed regions of the structure.

(2) Members and joints found overstressed should be strengthened. Joints with low fatigue lives may be improved either by strengthening or grinding the welds. If grinding is used, the details of the grinding are to be submitted to the Society for review and approval.

(3) Interval of future Periodical Surveys should be determined based on the remaining fatigue lives of these joints.

402. Reuse

1. General

(1) The classification of a structure to be reused requires special considerations with respect to the review, surveys, structural analyses, and the removal and reinstallation operation.

(2) The requirements described in 401. whenever applicable and survey requirements given in 304. 5. for structure reuse.

(3) Since the structure is to be reused at a new site, the environmental and geotechnical data used in the analysis should be in accordance with those for the new site.

(4) The structure reuse involves the structure removal and reinstallation process which requires special plans in order to achieve its intended services.

2. Removal and reinstallation operation

(1) The structure removal procedure shall be well planned and analyzed to verify that the integrity of the structure has not been compromised.

(1) Structure removal plans, procedures, sea-fastening drawings, transportation, together with the analysis calculations should be submitted to the Society for review.

(3) In general, Ch 4, Sec 9 should be followed for the reinstallation of used structures. ¶
CHAPTER 3 MATERIALS AND WELDINGS

Section 1 Materials

101. General

1. Application

(1) The requirements in this Chapter apply to the structural steels and materials for concrete construction intended to be used for the construction of offshore structure.

(2) The requirements, other than those specified in this chapter, are to be in accordance with the related requirements of Pt 2, Ch 1 of Rules for Classification of Steel Ships.

(3) All materials used for a structure requiring Classification Survey during Construction are to be manufactured under approved method or under alternative process considered equivalent to the approved method and are to be adequate to the relevant requirements of the Rules.

(4) Upon request of attending Surveyor, data as to place of origin and results of relevant material tests for structural materials is to be submitted by the fabricator.

2. Steel Forming

(1) When forming changes base plate properties beyond acceptable limits, appropriate heat treatments are to be carried out to reestablish required properties. Unless approved otherwise, the acceptable limits of the reestablished properties should meet the minimums specified for the original material before forming.

(1) The Society will survey formed members for their compliance with the forming dimensional tolerances required by the design.

102. Structural steels

1. Application

This requirement covers specifications for materials used for the construction of offshore steel structures. It is not intended for metals used in reinforced or prestressed concrete.

2. Materials selection

(1) Materials used are required to exhibit satisfactory formability and weldability characteristics. As required, documentation is to be submitted to substantiate the applicability of a proposed steel.

(2) The requirements of (A) to (C) are to be considered as selection of materials.

(A) Toughness

Materials are to exhibit fracture toughness which is satisfactory for the intended application as supported by previous satisfactory service experience or appropriate toughness tests. Where the presence of ice is judged as a significant environmental factor, material selection may require special consideration.

(B) Corrosion control

Details of corrosion control systems (such as coatings, sacrificial anodes or impressed current systems) are to be submitted with adequate supporting data to show their suitability. Such information is to indicate the extent to which the possible existence of stress corrosion, corrosion fatigue, and galvanic corrosion due to dissimilar metals to be considered. Where the intended sea environment contains unusual contaminants, any special corrosive effects of such contaminants should also be considered. Appropriate coatings may be used to achieve satisfactory corrosion protection for miscellaneous parts such as bolts and nuts.

(C) Through thickness stress

In cases where through thickness properties relating to the structural design, the use of special steel with improved through thickness properties specified in Pt 2, Ch 1, 310. of Rules for Classification of Steel Ships may be required.

(3) Bolts and nuts are to have mechanical and corrosion characteristics comparable to the structural elements being joined and are to be manufactured and tested in accordance with recognized material standards.
3. Kinds of steels

(1) Steels are classified as specified in Table 2.1.1 and Table 2.1.2.

Notes
(1) Steels are to be classified as follows according to their tensile strength.
  Group I: 275 N/mm² max.
  Group II: 276 ~ 415 N/mm²
  Group III: 416 ~ 690 N/mm²
(2) To 50 mm thick for Group I, fully killed and fine grain treatments.

</tbody>
</table>

Note (1) Steels are to be classified as follows according to their yield strength.

Group I : 275 N/m²·mm² max.
Group II : 276 ~ 415 N/m²·mm²

(2) Steels other than those mentioned therein may be used, provided that their chemical composition, mechanical properties and weldability are similar to those listed.

4. Mechanical properties

(1) Satisfactory mechanical properties can be demonstrated by any one of the following.
(A) Demonstration of past successful application, under comparable conditions, of a steel, produced to a recognized standard. (such as those of the ASTM, API or other recognized standard)
(B) Demonstration that a steel manufactured by a particular producer using a specific manufacturing process has minimum toughness levels representative of those listed Table 2.1.1 and Table 2.1.2.
(C) Charpy impact testing in accordance with Table 2.1.3.

(2) Impact tests
(A) Impact test temperature and absorbed energy of steels comply with Table 2.1.3.
(B) Energy values in Table 2.1.3 are minimum average values for full-size longitudinal specimens, Alternative toughness criteria which may be applied are as follows:
(a) Subsized longitudinal specimens:
   To comply with Pt 2, Ch 1, Sec 2 of Rules for Classification of Steel Ships.
(b) Transverse specimens:
   2/3 of the energy values shown in Table 2.1.3 but in no case less than 20 J.
(c) Longitudinal or transverse specimens: lateral expansion should not be less than 0.5 mm, or 0.38 mm, respectively
(d) Nil-ductility temperature (NDT) as determined by drop weight tests should be 5°C below the test temperature indicated in Table 2.1.3, notes (2).
(e) Other fracture toughness tests as appropriate by the Society.
(C) The minimum number of specimens to be tested per heat should be three; however, this number should be increased in accordance with usage of the material(see ASTM A673 or equivalent).

**NOTES**

(1) \( L \) direction denotes that the longitudinal axis of the test specimen is arranged parallel to the final direction of rolling.

(2) The following (i) to (iv) apply in accordance with minimum service temperature of steels, test requirements for service temperatures down to -30°C for lower service temperatures are to be specially considered.

(i) For structural members and joints whose performance is vital to the overall integrity of the structure and which experience an unusually severe combination of stress concentration, rapid loading, cold working, and restraint, the absorbed energy of impact test shall be met at test temperatures as given below.

<table>
<thead>
<tr>
<th>Group</th>
<th>Test temperature (°C)</th>
<th>Minimum service temperature (°C)</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td></td>
<td>-50</td>
<td>-30</td>
</tr>
</tbody>
</table>

(iii) For primary structural members subjected to significant tensile stresses and whose usage warrants impact toughness testing, the absorbed energy of impact test should be met at the following test temperatures.

<table>
<thead>
<tr>
<th>Group</th>
<th>Test temperature (°C)</th>
<th>Minimum service temperature (°C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>I , II</td>
<td>minimum service temperature</td>
<td>As determined 201. 5</td>
</tr>
</tbody>
</table>

(iv) For structural members which have sufficient structural redundancy so that their fracture would not pose a threat to the survivability of the structure, the toughness criteria specified for (iii) above may be relaxed provided the materials used in such cases are appropriate for the loading conditions, loading rates, and temperatures encountered in service.
5. Minimum Service Temperature

Minimum service temperature is generally to be established in accordance with (1) to (3) below. This temperature is to be based on meterological data taken over a period of not less than 10 years for the lowest average daily temperature.

(1) Material below the Splash Zone
For material below the Splash Zone below the splash zone, the service temperature is defined as 0°C. A higher service temperature maybe used where deemed appropriate by the Society.

(2) Material within or above the Splash Zone
For material within or above the splash zone the service temperature is the same as the lowest average daily atmospheric temperature. A higher service temperature may be used if the material above the waterline is warmed by adjacent sea water temperature or by auxiliary heating.

(3) Special Conditions
In all cases where material temperature is reduced by localized cryogenic storage or other cooling conditions, such factors should be taken into account in establishing minimum service temperature.

103. Materials for Concrete Construction

1. General

(1) Application
This subsection covers specifications for materials for concrete used in the construction of offshore platforms. It includes the metals used in reinforced or prestressed concrete. All materials are to be suitable for intended service conditions and are to be of good quality, defined by recognized specifications and free of injurious defects. Materials used in the construction of concrete structures are to be selected with due attention given to their strength and durability in the marine environment.

(2) Zones
Particular attention should be given in each of the following zones.
(A) Submerged zone
   chemical deterioration of the concrete, corrosion of the reinforcement and hardware, and abrasion of the concrete
(B) Splash zone
   freeze-thaw durability, corrosion of the reinforcement and hardware, chemical deterioration of the concrete, and fire hazards
(C) Ice zone
   freeze-thaw durability, corrosion of the reinforcement and hardware, chemical deterioration of the concrete, fire hazards, and abrasion of the concrete
(D) Atmospheric zone
   freeze-thaw durability, corrosion of reinforcement and hardware, and fire hazards

2. Cement

(1) Type
Cement is to be equivalent to Types I or II Portland cement as specified by ASTM C150 or portland-pozzolan cement as specified by ASTM C595. ASTM C150 Type III Portland cement may be specially approved for particular applications by the Society.

(2) Tricalcium Aluminate
The tricalcium aluminate content of the cement is generally to be in the 5% to 10% range.

(3) Oil Storage
For environments which contain detrimental sulfur bearing materials (such as where oil storage is planned and the oil is expected to contain sulphur compounds which are detrimental to concrete durability), the maximum content of tricalcium aluminate is to be at the lower end of the 5% to 10% range. Alternatively, pozzolans or pozzolans and fly ash may be added or a suitable coating employed to protect the concrete.

3. Water

(1) Cleanliness
Water used in mixing concrete is to be clean and free from injurious amounts of oils, acids, alkanes, salts, organic materials or other substances that may be deleterious to concrete or steel.

(2) Nonpotable Water
If nonpotable water is proposed for use, the selection of proportions of materials in the concrete is to be based on test concrete mixes using water from the same source. The strength of mortar test cylinders made with nonpotable water is not to be less than 90% of the strength of similar cylinders made with potable water. Strength test comparisons should include 7-day and 28-day strength data on mortars prepared and tested in accordance with recognized standards such as ASTM C 109.

4. Chloride or Sulphide Content

(1) Water for structural concrete or grout should not contain more than 0.07% chlorides as Cl by weight of cement, nor more than 0.09% sulfates as SO₄ when tested by ASTM D 512. Chlorides in mix water for prestressed concrete or grout should be limited to 0.04% by weight of cement.

(2) Total chloride content, as Cl, of the concrete prior to exposure shall not exceed 0.10% by weight of the cement for normal reinforced concrete and 0.06% by weight of cement for prestressed concrete.

5. Aggregates

(1) General

Aggregates are to conform to the requirements of ASTM C 33 or equivalent. Other aggregates may be used if there is supporting evidence that they produce concrete of satisfactory quality. When specially approved, lightweight aggregates similar to ASTM C 330 may be used for conditions that do not pose durability problems.

(2) Washing

Marine aggregates are to be washed with fresh water before use to remove chlorides and sulfates so that the total chloride and sulphate content of the concrete mix does not exceed the limits defined in 102. 4.

(3) Size

The maximum size of the aggregate is to be such that the concrete can be placed without voids. It is recommended that the maximum size of the aggregate should not be larger than the smallest of the following.

(A) one-fifth of the narrowest dimension between sides of forms
(B) one-third of the depth of slabs
(C) three-fourths of the minimum clear spacing between individual reinforcing bars, bundles of bars, prestressing tendons or post-tensioning ducts.

6. Admixtures

(1) General

The admixture is to be shown capable of maintaining essentially the same composition and performance throughout the work as the product used in establishing concrete proportions. Admixtures containing chloride ions are not to be used if their use will produce a deleterious concentration of chloride ions in the mixing water.

(2) Recognized Standards

Admixtures are to be in accordance with applicable recognized standards such as ASTM C 260, ASTM C 494, ASTM C 618 or equivalents.

(3) Pozzolan Content

Pozzolan or pozzolan and fly ash content is not to exceed 15% by weight of cement unless specially approved.

7. Steel Reinforcement

Steel reinforcement used in offshore concrete structures is to be suitable for its intended service and in accordance with recognized standards.

(1) Reinforcement for Non-Prestressed Concrete

Non-prestressed reinforcement is to be in accordance with one of the following specifications or its equivalents.

(A) Deformed reinforcing bars and plain bars: ASTM A 615
(B) Bar and rod mats: ASTM A 184
(C) Plain wire for spiral reinforcement: ASTM A82, ASTM A 704
(D) Welded plain wire fabric: ASTM A 185
(E) Deformed wire: ASTM A 496
(F) Welded deformed wire fabric: ASTM A 497
(2) Welded reinforcement
Reinforcement which is to be welded is to have the properties needed to produce satisfactory welded connections. Welding is to be in accordance with Pt 2, Ch 2 of Rules for Classification of Steel Ships.

(3) Steel Reinforcement for Prestressed Concrete
Steel reinforcement for prestressed concrete is to be in accordance with one of the following specifications or equivalent.
- Seven-wire strand: ASTM A416, Wire: ASTM A 42

(4) Other prestressing tendons may be approved upon presentation of evidence of satisfactory properties.

8. Concrete
The concrete is to be designed to assure sufficient strength and durability. A satisfactory method for quality control of concrete is to be used which is equivalent to ACI 318. Mixing, placing and curing of concrete shall conform to recognized standards.

9. Water–Cement Ratio
Unless otherwise approved, water-cement ratios and 28-day compressive strengths of concrete for the three exposure zones are to be in accordance with Table 2.1.4.

<table>
<thead>
<tr>
<th>Zone</th>
<th>Maximum W/C Ratios</th>
<th>Minimum 28-day Cylinder Compressive Strength</th>

</thead>
<tbody>
<tr>
<td>Submerged</td>
<td>0.45</td>
<td>35 MPa min.</td>
</tr>
<tr>
<td>Splash and Atmospheric</td>
<td>0.40–0.45*</td>
<td>35 MPa min.</td>
</tr>
</tbody>
</table>

*Depending upon severity of exposure

10. Other Durability Requirements
(1) Cement
Minimum cement content should insure an adequate amount of paste for reinforcement protection and generally be not less than 355 kg/m³.

(2) Freeze-Thaw Durability
When freeze-thaw durability is required, the concrete is to contain entrained air in accordance with a recognized standard such as ACI 211.1. Attention is to be paid to the appropriate pore distribution of the entrained air and the spacing between pores in the hardened concrete. The calculated spacing factors are not to exceed 0.25 mm.

(3) Scouring
When severe scouring action is expected, the coarse aggregate should be as hard as the material causing the abrasion, the sand content of the concrete mix should be kept as low as possible, and air entrainment is to be limited to the minimum appropriate to the application.

11. Grout for Bonded Tendons
(1) General
Grout for bonded tendons is to conform to ACI 318 or equivalent.

(2) Chlorides and Sulphates
Grout is not to contain chlorides or sulfates in amounts which are detrimental to the structure. Limitations are included in 103.4.

(3) Contents
Grout is to consist of Portland cement and potable water, or Portland cement, sand, and potable water. Admixtures may be used only after sufficient testing to indicate that their use is beneficial and that they are free of harmful quantities of chlorides, nitrates, sulfides, sulphates or any other material which has been shown to be detrimental to the steel or grout.

(4) Sand
Sand, if used, is to conform to ASTM C144 or equivalent, except that gradation may be modified as necessary to obtain increased workability.
(5) Preparation
Proportions of grouting materials are to be based on results of tests on fresh and hardened grout prior to beginning work. The water content shall be the minimum necessary for proper placement but in no case more than 50% of the content of cement by weight. Grout is to be properly mixed and screened.

(6) Temperature
Temperature of members at the time of grouting is to be above 10°C and is to be maintained at this temperature for at least 48 hours.
Appendix 3–1  Material Selection

1. General
   (1) For the classification of offshore fixed structures, it is necessary to take into account minimum excepted service temperature, the structural element category and material thickness when selecting structural materials.
   (2) The various parts of the structure are to be grouped according to their material application categories. The structural elements falling into these categories are described in general, in Par 3.

2. Classification of Application
   The application of structural members in an offshore fixed structure is to be in accordance with the categories listed in this paragraph.
   (1) Special application refers to highly stressed materials, located at intersections of main structural elements and other areas of high stress connection where the occurrence of a fracture could induce a major structural failure.
   (2) Primary application refers to primary load carrying members of a structural where the occurrence of a fracture could induce a major structural failure.
   (3) Secondary application refers to less critical members due to a combination of lower stress and favorable geometry or where an incidence of fracture is not likely to induce a major structural failure.

3. Examples of Applications
   The following are typical examples of application categories.
   (1) a Secondary Application Structure (Least Critical)
      (A) Internal structure including bulkheads and girders in legs or columns
      (B) Deck plating not essential for overall structural integrity
      (C) Low stressed deck beams in parallel and bracing, except where structure is considered primary or special application
      (D) Plating of certain columns with low slenderness ratio, except at intersections
   (2) Primary Application Structure (intermediate)
      (A) Plating of lattice legs
      (B) External shell plating of caissons
      (C) Deck plating and structure which is not considered special or secondary
      (D) Main braces, jacket legs and deck legs, except where considered special
      (E) Heavy flanges and deep webs of major load supporting members, which from box or I type supporting structure, and which do not receive major concentrated loads
      (F) Members which provide local reinforcement or continuity of structure in way of intersections, including main deck load plating where the structure is considered special application
   (3) Special Application (Most Critical)
      (A) External shell or deck structure in way of intersections of vertical columns
      (B) Portions of deck plating, heavy flanges and deep webs at major load supporting members within the deck, which from box or I type supporting structure, and which receive major concentrated loads
      (C) Intersection of major bracing members and critical joint nodes
      (D) Members which receive immediate concentrated loads at intersections of major structural members

4. Steel Section Criteria
   (1) Table 2–1 shows selection criteria for each structural element category for grades of normal and higher strength structural steel for hull specified in Pt 2, Ch 1 of Rules for Classification of Steel Ships.
   (2) Selection of steel grades and thickness other than those shown in above (1) should be based on the fundamental principles specified in Table 2–1 and Ch 3, 201. 3.

</table>
Section 2 WELDING

201. General

1. Application

(1) Welding for steel structures is to comply with these requirements and Pt 2, Ch 2 of Rules for Classification of Steel Ships.

(2) Where deemed appropriate by the Society, National Standards, internationally recognized Codes or standards considered as equivalent for those may be applied instead of requirements of this Chapter.

2. Matters to be approved

(1) Qualification of Welding Procedures

(A) Welding procedure qualification test (WPQT), in general, apply to the requirements specified in Pt 2, Ch 2, Sec 4 of Rules for Classification of Steel Ships.

(B) Procedures for the welding of all joints, including types of electrodes, edge preparations, welding techniques and proposed positions, are to be established before construction begins.

(C) Details of proposed welding procedures and sequences may be required to be submitted for review, depending on the intended application. Special precautions, with regard to joint preparation, preheat, welding sequence, heat input and interpass temperature, are to be taken for welding thick sections.

(D) Ultrasonic inspection to insure the absence of injurious laminations may be required for material used where through thickness (Z-direction) properties are important.

(2) Welder

All welders to be employed in the construction of structure are to be qualified in the requirements of Pt 2, Ch 2, Sec 5 of Rules for Classification of Steel Ships or considered as equivalent.

202. Welding works and inspection

1. Plans and Specifications

(1) Submitted plans or specifications are to be in accordance with Ch 4, Sec 1 and they are to indicate clearly the extent of welding for the main parts of the structure and the extent of non-destructive inspection of the weld.

(2) The welding process, filler metal and joint design are to be indicated on plans or in separate specifications submitted for approval, which are to distinguish between manual and automatic welding.

(3) The Surveyor is to be informed of the planned sequences and procedures to be followed in the erection and welding of the main structural members.

(4) In all instances, welding procedures and filler metals are to be applied which will produce sound welds that have strength and toughness comparable to that of the base material.

2. Preparation for Welding

(1) Edge Preparation and Fitting

(A) Edge preparations are to be accurate and uniform and the parts to be welded are to be fitted in accordance with the approved joint detail. All means adopted for correcting improper fitting are to be to the satisfaction of the Surveyor.

(B) Where excessive root openings are encountered for butt weld connections, weld build-up of the edges may be approved by the Surveyor, depending upon the location of the joint and the welding procedures employed. Unless specially approved, such build-up of each edge, where permitted, is not to exceed t/2 or 12.5 mm, whichever is less, where t is the thickness of the thinner member being welded.

(C) Where sections to be butt welded differ in thickness and have an offset on any side of more than 3 mm, a suitable transition taper length is to be provided. In general, the transition taper length is to be not less than three times the offset. The transition may be formed by tapering the thicker member or by specifying a weld joint design which will provide the required transition.

(2) Alignment
Means are to be provided for maintaining the members to be welded in correct position and alignment during the welding operation. In general, strongbacks or other appliances used for this purpose are to be so arranged as to allow for expansion and contraction during production welding. The removal of such items is to be carried out to the satisfaction of the Surveyor.

(3) Cleanliness
(A) All surfaces to be welded are to be free from moisture, grease, loose mill scale, excessive rust and paint. Primer coatings of ordinary thicknesses, thin coatings of linseed oil or equivalent coatings may be used, provided it is demonstrated that their use has no adverse effect on the production of satisfactory welds.
(B) Slag and scale are to be removed not only from the edges to be welded but also from erich pass or layer before the deposition of subsequent passes or layers. Weld joints prepared by arc-air gouging may require additional preparation by grinding or chipping and wire brushing prior to welding, to minimize the possibility of excessive carbon on the surfaces.
(C) Compliance with these cleanliness requirements is of prime importance in the welding of higher strength steels, especially those which are quenched and tempered.

(4) Tack Welds
Tack welds of consistent good quality, made with the same grade of filler metal as intended for production welding and deposited in such a manner as not to interfere with the completion of the final weld, need not be removed, provided they are found upon examination to be thoroughly clean and free from cracks or other defects. Preheat may be necessary prior to tack welding when the materials to be joined are highly restrained. Special consideration is to be given to using the same preheat as specified in the welding procedure when tack welding higher-strength steels, particularly those materials which are quenched and tempered. These same precautions are to be followed when making any permanent welded markings.

(5) Run-on and Run-off Tabs
When used, run-on and run-off tabs are to be designed to minimize the possibility of high stress concentrations and base-metal and weld-metal cracking.

3. Production Welding

(1) Environment
Proper precautions are to be taken to insure that all welding is done under conditions where the welding site is protected against the deleterious effects of moisture, wind, and severe cold.

(2) Sequence
Welding is to be planned to progress symmetrically so that shrinkage on both sides of the structure will be equalized. The ends of frames and stiffeners should be left unattached to the plating at the subassembly stage until connecting welds are made in the intersecting systems of plating, framing and stiffeners at the erection stage. Welds are not to be carried across an unwelded joint or beyond an unwelded joint which terminates at the joint being welded, unless specially approved.

(3) Preheat and Postweld Heat Treatment
(A) The use of preheat is to be considered when welding higher-strength steels, materials of thick cross section, materials subject to high restraint, and when welding is performed under high humidity conditions or when the temperature of the steel is below 0°C.
(B) The control of interpass temperature is to be specially considered when welding quenched and tempered higher-strength steels.
(C) When preheat is used, the temperature is to be in accordance with the accepted welding procedure. Post-weld heat treatment, when specified, is to be carried out using an approved method.

(4) Low-hydrogen Electrodes or Welding Processes
Unless otherwise approved, the use of low-hydrogen electrodes or welding processes is required for welding all higher-strength steels, and may also be considered for normal-strength steel weldments subject to high restraint. When using low-hydrogen electrodes or processes, proper precautions are to be taken to ensure that the electrodes, fluxes and gases used for welding are clean and dry.

(5) Back Gouging
Chipping, grinding, arc-air gouging or other suitable methods are to be employed at the root or underside of the weld to obtain sound metal before applying subsequent beads for all full penetration welds. When arc-air gouging is employed, the selected technique is to minimize carbon
buildup and burning of the weld or base metal. Quenched and tempered steels are not to be flame gouged using oxy-fuel gas.

(6) Peening
The use of peening is not recommended for single-pass welds and the root or cover passes on multipass welds. Peening, when used to correct distortion or to reduce residual stresses, is to be effected immediately after depositing and cleaning each weld pass.

(7) Faring and Flame shrinking
(A) Fairing by heating or flame shrinking, and other methods of correcting distortion or defective workmanship in fabrication of main strength members and other members which may be subject to high stresses, are to be carried out only with the expressed approval of the Surveyor.
(B) These corrective measures are to be kept to an absolute minimum when higher-strength quenched and tempered steels are involved, due to high local stresses and the possible degradation of the mechanical properties of the base material.

(8) Weld Soundness and Surface Appearance
(A) Production welds are to be sound, crack free and reasonably free from lack of fusion or penetration, slag inclusions and porosity.
(B) The surfaces of welds are to be visually inspected and are to be regular and uniform with a minimum amount of reinforcement and reasonably free from undercut and overlap and free from injurious arc strike.
(C) Contour grinding when required by an approved plan or specification or where deemed necessary by the Surveyor is to be carried out to the satisfaction of the Surveyor.

4. Inspection of Welds
(1) Inspection of welded joints in important locations is to be partied out preferably by established non destructive test methods such as radiographic, ultrasonic, magnetic-particle or dye-penetrant inspection.
(2) An approved acceptance criterion by the Society or Guidance relating to Pt 2, Annex 2-9 of Rules for Classification of Steel Ships "Guidance for Radiographic and Ultrasonic Inspection of Hull Welds" are to be used in evaluating radiographs and ultrasonic indications(see Appendix 3-2).
(3) Radiographic or ultrasonic inspection, or both, are to be used when the overall soundness of the weld cross section is to be evaluate. Magnetic-particle or dye-penetrant inspection may be used when investigating the outer surface of welds, as a check of intermediate weld passes such as root passes, and to check back chipped, ground or gouged joints prior to depositing subsequent passes.
(4) Surface inspection of important tee or corner joints in critical locations, using an approved magnetic-particle or dye-penetrant method, is to be conducted to the satisfaction of the Surveyor.
(5) Some steels, especially higher-strength may be susceptible to delayed cracking. When welding these materials, the final nondestructive testing is to be delayed for a suitable period to permit detection of such defects. Weld run-on or run-off tabs may be used where practicable and these may be sectioned for examination.
(6) The practice of taking weld plugs or samples by machining or cutting from the welded structure is not recommended and is to be used only in the absence of other suitable inspection methods. When such weld plugs or samples are removed from the welded structure, the holes or cavities thus formed are to be properly prepared and welded, using a suitable welding procedure as established for the original joint.

5. Repair Welding
(1) Defective welds and other injurious defects, as determined by visual inspection, nondestructive test methods, or leakage under hydrostatic tests, are to be excavated in way of the defects to sound metal and corrected by rewelding, using a suitable repair welding procedure to be consistent with the material being welded.
(2) Removal by grinding of minor surface imperfections such as scars, tack welds and arc strikes may be permitted.
(3) Special precautions, such as the use of both preheat and low-hydrogen electrodes, are to be considered when repairing welds in higher-strength steel, materials of thick cross section or materials subject to high restraint.
6. Butt Welds

(1) Manual Welding Using Stick Electrodes
   (A) Manual welding using stick electrodes may be employed for butt welds in members not exceeding 6.5 mm in thickness without beveling the abutting edges. Members exceeding 6.5 mm are to be prepared for welding using an appropriate edge preparation, root opening and root face(land) to provide for welding from one or both sides.
   (B) For welds made from both sides, the root of the first side welded is to be removed to sound metal by an approved method before applying subsequent weld passes on the reverse side.
   (C) When welding is to be deposited from one side only, using ordinary welding techniques, appropriate backing(either permanent or temporary) is to be provided. The backing is to be fitted so that spacing between the backing and the members to be joined is in accordance with established procedures. Unless specially approved otherwise, splices in permanent backing strips are to be welded with full penetration welds prior to making the primary weld.

(2) Submerged-arc Welding
   (A) Submerged-arc welding, using wire-flux combinations for butt welds in members not exceeding 16 mm in thickness, may be employed without beveling the abutting edges. Members exceeding 16 mm are normally to be prepared for welding using an appropriate edge preparation, root opening and root face(land) to provide for welding from one or both sides.
   (B) When it is determined that sound welds can be made without gouging, the provisions of 202.3(5) are not applicable. Where the metal is to be deposited from one side only, using ordinary welding techniques, backing(either permanent or temporary) is to be provided and the members are to be beveled and fitted in accordance with established procedures.

(3) Gas Metal-arc and Flux Cored-arc Welding
   Manual semi-automatic or machine automatic gas metal-arc welding, and flux cored-arc welding using wire-gas combinations and associated processes, may be ordinarily employed utilizing the conditions specified in (1) except that specific joint designs may differ between processes.

(4) Electroslag and Electrogas Welding
   The use of electroslag and electrogas welding processes will be subject to special consideration, depending upon the specific application and the mechanical properties of the resulting welds and heat-affected zones.

(5) Special Welding Techniques
   (A) Special welding techniques employing any of the basic welding processes mentioned in (1) through (4) will be specially considered, depending upon the extent of the variation from the generally accepted technique.
   (B) Such special techniques include one side welding, narrow gap welding, tandem-arc welding, open-arc welding and consumable-nozzle electroslag welding. The use of gas tungsten-arc welding will also be subject to special consideration, depending upon the application and whether the process is used manually or automatically.

7. Fillet Welds

(1) General
   (A) The sizes of fillet welds are to be indicated on detail plans or on a separate welding schedule and are subject to approval.
   (B) The weld throat size is not to be less than 0.7 times the weld leg size. Fillet welds may be made by an approved manual or automatic technique.
   (C) Where the gap between the faying surfaces of members exceeds 2 mm and is not greater than 5 mm, the weld leg size is to be increased by the amount of the opening. Where the gap between members is greater than 5 mm, fillet weld sizes and weld procedures are to be specially approved by the Surveyor. Completed welds are to be to his satisfaction.
   (D) Special precautions such as the use of preheat or low-hydrogen electrodes or low hydrogen welding processes may be required Where small fillets are used to attach heavy members or sections. When heavy sections are attached to relatively light members, the weld size may be required to be modified.

(2) Tee Connections
   Except where otherwise indicated under (1) the fillet weld requirement for tee connections is to be determined by the lesser thickness member being joined. Where only the webs of girders, beams or stiffeners are to be attached, it is recommended that the unattached face plates or flanges be cut back. Except for girders of thickness greater than 25 mm, reduction in fillet weld
sizes may be specially approved in accordance with either (A) or (B) specified below. However, in no case is the reduced leg size to be less than 5 mm.

(A) Where quality control facilitates working to a gap between members being attached of 1 mm or less, a reduction in fillet weld leg size of 0.5 mm may be permitted provided that the reduced leg size is not less than 8 mm.

(B) Where automatic double continuous fillet welding is used and quality control facilitates working to a gap between members being attached of 1 mm or less, a reduction in fillet weld leg size of 1.5 mm may be permitted provided that the penetration at the root is at least 1.5 mm into the members being attached and the reduced leg size is not less than 5 mm.

(3) Lapped Joints
Lapped joints are generally not to have overlaps of less width than twice the thinner plate thickness plus 25 mm. Both edges of an overlapped joint are to have continuous fillet welds in accordance with (1) or (4).

(4) Overlapped End Connections
Overlapped end connections of structural members which are considered to be effective in the overall strength of the unit are to have continuous fillet welds on both edges equal in leg size to the thickness of the thinner of the two members joined. All other overlapped end connections are to have continuous fillet welds on each edge of leg sizes such that the sum of the two is not less than 1.5 times the thickness of the thinner member.

(5) Overlapped Seams
Unless specially approved, overlapped seams are to have continuous welds on both edges of the sizes required by the approved plans and are to be in accordance with the applicable provisions of (1).

(6) Plug Welds or Slot Welds
(A) Plug welds or slot welds may be specially approved for particular applications.
(B) Where used in the body of doublers and similar locations, such welds may be generally spaced about 300 mm between centers in both directions.
(C) Slot welds generally should not be filled with weld metal. For plate thicknesses up to 13 mm, fillet sizes are to be equal to plate thickness but not greater than 9.5 mm for thicknesses over 13 mm to 25 mm fillet sizes are to be 16 mm maximum.

8. Full Penetration Corner or Tee Joints
Measures taken to achieve full penetration corner or tee joints, where specified, are to be to the satisfaction of the attending Surveyor. Ultrasonic inspection of the member in way of the connection may be required to assure the absence of injurious laminations prior to fabrication which could interfere with the attainment of a satisfactory welded joint.
Appendix 3-2  Guidance for non-destructive inspection for construction of offshore structure

1. Applications

These requirements apply to radiographic and ultrasonic inspection for construction of offshore structure.

2. Extent of Inspection of Welds

(1) General

(A) The minimum extent of nondestructive testing to be conducted is indicated in (4) or (5) below. The distribution of inspected welds is to be based on the classification of application of the welds, as mentioned in (3) and the variety of weld sizes used in the structure.

(B) Nondestructive testing is generally to be carried out after all forming and postweld heat treatment, and procedures should be adequate to detect delayed cracking. Welds which are inaccessible or difficult to inspect in service are to be subjected to increased levels of non-destructive inspection.

(C) Nondestructive examination of full penetration butt welds is generally to be carried out by radiographic or ultrasonic methods. Where a method (such as radiography or ultrasonics) is selected as the primary nondestructive method of inspection, the acceptance standards of such a method govern.

(D) Where inspection by any method indicates the presence of defects that could jeopardize the integrity of the structure, removal and repair of such defects are to be carried out to the satisfaction of the attending Surveyor.

(E) Should the ultrasonic method be used as the primary inspection method, such testing should be supplemented by a reasonable amount of radiographic inspection to determine that adequate quality control is being achieved.

(F) To assess the extent of surface imperfections in welds made in Group III steels used in critical structural locations, representative inspection by the magnetic-particle or dye-penetrant method should also be accomplished.

(2) Plans

A plan for nondestructive testing of the structure is to be submitted. This plan should include, but not be restricted to, visual inspection of all welds, representative magnetic-particle or dye-penetrant inspection of tee and fillet welds not subjected to ultrasonic inspection, and the inspection of all field welds by appropriate means. The extent and method of inspection are to be indicated on the plan, and the extent of inspection is to be based on the function of the structure and the accessibility of the welds after the structure is in service. For automated welds for which quality assurance techniques indicate consistent satisfactory performance a lesser degree of inspection may be permitted.

(3) Classification of Application

Welds are to be designated as being either special, primary or secondary depending on the function and severity of service of the structure in which the welds are located. Special welds are those occurring in structural locations of critical importance to the integrity of the structure or its safe operation. Secondary welds are those occurring in locations of least importance to the overall integrity of the structure. Primary welds are those occurring in locations whose importance is intermediate between the special and secondary classifications. Reference can be made to Appendix 3-1 for examples of applications following this classification system.

(4) Extent of Nondestructive inspection - Steel Jacket Type Structures

In general, the number of penetration type welds (i.e., butt, T, K and Y. joints) to be inspection each classification is to be based on the percentages stated below. Alternatively, the extent of radiographic and ultrasonic inspection may be based on other methods, provided the alternative will not result in a lesser degree of inspection. Where the extent of welds to be inspected is stated as a percentage, such as 20% of primary welds, this means that complete inspection of 20% of the total number of welds considered to be primary is required.

(A) All welds considered special are to be inspected 100% by the ultrasonic or radiographic method.

(B) Twenty percent of all welds considered primary are to be inspected by the ultrasonic or radiographic method.
(C) Welds considered to be secondary are to be inspected on a random basis using an appropriate method.

(D) In locations where ultrasonic test results are not considered reliable, the use of magnetic-particle or dye-penetrant inspection as a supplement to ultrasonic inspection is to be conducted. For T, K, or Y joints, approval may be given to substituting magnetic-particle or dye-penetrant inspection for ultrasonic inspection when this will achieve a sufficient inspection quality.

(E) Magnetic-particle or dye-penetrant inspection of fillet welds is to be accomplished for
- all permanent fillet welded in jacket construction
- all jacket-to-pile shim connections, and
- all fillet welds in special application areas the deck structure.
- The random inspection of other deck fillet welds is to be carried out at the discretion of the Surveyor.

(5) Extent of Nondestructive Inspection Steel Plate or Shell Type Structures

The minimum extent of the ultrasonic or radiographic inspection of plate or shell type structures is to be equivalent to, or in general agreement with, the number of check points obtained by the following equations. As practicable, the length of each checkpoint is to be at least 750 mm.

(A) For structures which are rectangular in shape

\[ n = \frac{L(B + D)}{46.5} \]

where,

- \( n \) = number of check points (2 is minimum number)
- \( L \) = length of greatest dimension of structure, in m
- \( B \) = greatest breadth, in m
- \( D \) = greatest depth at the center, in m

(B) For structures which are other than rectangular a proportional number of check points should be supplied.

(C) For structures which are circular in shape

\[ n = \frac{Ld}{46.5} \]

where,

- \( n \) = number of check points (2 is minimum number)
- \( L \) = length of the circular structure, in m
- \( d \) = diameter of the circular structure, in m

(6) Additional Inspection - Special Conditions

Additional inspection may be required depending on the type and use of the structure, the material and welding procedures involved, and the quality control procedures employed.

(7) Additional Inspection - Production Experience

If the proportion of unacceptable welds becomes abnormally high, the frequency of inspection is to be increased.

(8) High Through Thickness(Z-Direction) Stresses

At important intersections welds which impose high stresses perpendicular to the member thicknesses(Z-direction loading) are to be ultrasonically inspected to assure freedom from lamellar tearing after welding.
3. Acceptance Criteria

As stated in 202. 4 recognized acceptance criteria such as those issued by the AWS are to be employed. When employing Guidances relating to Pt 2, Annex 2–9 of Rules for Classification of Steel Ships "Guidance for Radiographic and Ultrasonic Inspection of Hull Welds", Class 1 and Class 2 criteria are to be applied as follows.

(1) Class 1
   Acceptance criteria are to be used for special application structure and critical locations within primary application structure such as circumferential welds of cylindrical and built up columns or legs, weld intersections of external plating in platforms, etc.

(2) Class 2
   Acceptance criteria are to be used for primary application structure where Class 1 acceptance does not apply

(3) Class 3
   Acceptance criteria are to be used for secondary application structure

(4) When radiographic or ultrasonic inspection is specified for other types of connections, such as partial penetration and groove type tee or corner welds, modified procedures and acceptance criteria are to be specified which adequately reflect the application.  ☹
CHAPTER 4 DESIGN OF STRUCTURES

Section 1 Definitions and Design Documentation

101. Definitions

1. Recurrence Period
   The recurrence period is a specified period of time which is used to establish design values of random parameters such as wave height.

2. Operator
   An operator is any person or organization empowered to conduct operations on behalf of the Owners of an installation.

3. Constructor
   A constructor is any person or organization having the responsibility to perform any or all of the following.
   (A) Fabrication
   (B) Erection
   (C) Inspection
   (D) Testing
   (E) Load-out
   (F) Transportation and installation

4. Platform Structures
   (1) Various types of offshore structures to which these Rules may be applied are defined below.
      (A) Pile Supported Platform
         This type of structure is characterized by slender foundation elements, or piles, driven into the sea floor.
      (B) Gravity Structure
         This type of structure rests directly on the sea floor. The geometry and weight of the structure are selected to mobilize the available cohesive and frictional strength components of the sea floor soil to resist loadings.
      (C) Compliant tower
         This type of structure has narrower and more flexible tower than the typical pile supported platform and is supported by piles.
      (D) Articulated Buoyant Tower
         This type of structure depends on buoyancy acting near the water surface to provide the necessary righting stability.
   (2) Additionally, these Rules may be employed, as applicable, in the classification of structural types not mentioned above (1) when they are to be used as permanent offshore installations.

102. Design Documentation

1. General
   The design documentation to be submitted is to include the reports, calculations, plans, and other documentation necessary to verify the structural design.

2. Design Documentation
   The contents of reports are to comply with the recommended list of items given below.
   (1) Environmental Consideration
      (A) Reports on environmental considerations are to describe all environmental phenomena appropriate to the areas of construction, transportation, and installation. The types of environmental phenomena to be accounted for, as appropriate to the type and location of the structure are as follows.
      (a) Wind
(b) Waves  
(c) Current  
(d) Temperature  
(e) Tide  
(f) Marine growth  
(g) Chemical components of air and water  
(h) Snow and ice  
(i) Earthquake  
(j) Other pertinent phenomena

(B) The establishment of the environmental parameters is to be based on appropriate original data or, when permitted, data from analogous areas. Demonstrably valid statistical models to extrapolate to long-term values are to be employed, and any calculations required to establish the pertinent environmental parameter should be submitted.

(C) Preferably, a report on the various environmental considerations is to present data and conclusions on the relevant environmental phenomena. The report is, however, required to separately present a summary showing the parameters necessary to define the Design Environmental Condition and Operating Environmental conditions. Where applicable, the likely environmental conditions, such as strength and ductility level earthquake, are to be experienced during the transportation of the structure to its final site.

(D) The report on environmental considerations may also contain the calculations which quantify the effects of loadings on the structure where these are not provided in other documentation.

(2) Foundation Data

(A) A report on foundation data is to present the results of investigations or, when applicable, data from analogous area on geophysical, geological and geotechnical considerations existing at and near the platform site. The manner in which such data is established and the specific items to be assessed are to be in compliance with 702. The report is to contain a listing of references to cover the investigation, sampling, testing, and interpretive techniques employed during and after the site investigation.

(B) The report is to include a listing of the predicted soil-structure interaction, such as p-y data, to be used in design. As appropriate to the planned structure, the items which may be covered are as follows.

(a) Axial and lateral pile capacities and response characteristics 
(b) The effects of cyclic loading on soil strength 
(c) Scour 
(d) Settlements and lateral displacements 
(e) Dynamic interaction between soil and structure 
(f) The capacity of pile groups 
(g) Slope stability, bearing and lateral stability 
(h) Soil reactions on the structure 
(i) Penetration resistance

(C) Recommendations relative to any special anticipated problem regarding installation are to be included in the report. Items such as the following are to be included in the report.

(a) Hammer size 
(b) Soil erosion during installation 
(c) Bottom preparation 
(d) Procedures to be followed should pile installation procedures significantly deviate from those anticipated.

(3) Materials and welding

(A) Reports on structural materials and welding may be required for metallic structures, concrete structures or welding procedures where materials and procedures are used which do not conform to those provided for in Ch 3.

(B) For metallic structures, when it is intended to employ new alloys not defined by a recognized specification, reports are to be submitted indicating the adequacy of the material’s metallurgical properties, fracture toughness, yield and tensile strengths, and corrosion resistance, with respect to their intended application and service temperatures.

(C) For concrete structures, when it is not intended to test or define material properties in accordance with applicable standards of this Society, a report is to be provided indicating the standards actually to be employed and their relative adequacy with respect to the corresponding relative standards which are recognized by this Society.
3. Calculation

(1) Calculations are to be submitted to verify the propriety of the planned design. These calculations are to be made out by logical and general methods. For the Computerized input and output type of calculations, the examination report of the program, program manual and user's manual are to be submitted if necessary.

(2) Design and analysis calculations are to be submitted for items relating to loadings, structural stresses and deflections for in-place and marine operations. In this regard, calculations are to be in general compliance with the items listed below.

(A) Loadings
   Calculations for loadings are to be submitted in accordance with Sec 3.

(B) Structural stress and deflections
   (a) The stress and deflection calculations to be submitted are to include, those required for nominal element or member stresses and deflections.
   (b) As applicable, and where required in subsequent sections of these Rules, calculations may also be required for the stresses in localized areas and structural joints, the dynamic response of the structure, and fatigue life of critical members and joints.
   (c) For pile supported structures, calculations for the stresses in piles and the load capacity of the connection between the structure and the pile are to be submitted.
   (d) For gravity structures, calculations are to be submitted for the effects of the soil's reaction on the structure.
   (e) When accounting for the stress resultants described above, and those resulting from consideration of marine operations (see Sec 9), calculations are to demonstrate the adequacy of the structural elements, members or local structure. Also, the calculations are to demonstrate, as applicable, that the deflections resulting from the applied loadings and overall structural displacement and settlement do not impair the structural performance of the platform.

(C) Marine operation
   As applicable, calculations are to be submitted in accordance with Sec 9.

(D) Other calculations
   As required, additional calculations which demonstrate the adequacy of the overall design are to be submitted. Such calculations should include those performed in the design of the corrosion protection system.

103. Plans and Other Data

1. General

Generally, structural plans and other data are to be submitted. These plans are to include the following.

(A) The plans including general specification of the installed site and the location of the structure.

(B) Design criteria including recurrence period used for environmental phenomena evaluation

(C) General arrangement of the installation

(D) The manual of safety and protection device

(E) Number of persons who live in the structure

(F) The lists of authorized Governments for the structure

(G) The list of new characteristics

(H) The brief manual of monitoring device

(I) The manual for procedure of transportation and installation

2. Plans and Other Data

Plans which are to be submitted in relation to the design of structures are defined below.

(A) Arrangement plans, elevations, and plan views.

(B) Plan views clearly showing in sufficient detail the overall configuration, dimension and layout of the structure, its facilities and foundation in relation to above (A)

(C) Layout plans indicating the locations of equipment and locations of the equipment loads and other design deck loads, fender loads, etc., which are imposed on the structure

(D) Structural plans indicating the complete structural arrangement, dimensions, member sizes, plating and framing, material properties, and details of connections and attachments; for concrete structures, arrangements and descriptions of reinforcement procedures for construction
are to be indicated
(E) Pile plans indicating arrangements, nominal sizes, thicknesses and penetration
(F) Welding details and procedures, and schedule of nondestructive testing
(G) Corrosion control systems
(H) Structural plans indicating the complete arrangements of structures, such as helideck, crane
pedestals, equipment foundations and manner of reinforcement, fendering, various houses and
other structures which are not normally considered vital to the overall structural integrity of
the offshore structure
(I) Various information in support of novel features utilized in the offshore structure design,
such as hydrostatic and stability curves, elements of any mooring system, etc.

Section 2 ENVIRONMENTAL CONDITIONS

201. General

1. General

The environmental conditions to which an offshore installation may be exposed during its life are
to be described using adequate data for the area in which the structure is to be transported and
installed. All data used are to be fully documented with the sources and estimated reliability of da-
ta noted.

202. Environmental Factors

1. Environment factors

(1) In general, the design of an offshore installation will require investigation of the following envi-
ronmental factors.
(A) Waves
(B) Wind
(C) Currents
(D) Tides and storm surges
(E) Air and sea temperatures
(F) Ice and snow
(G) Marine growth
(H) Seismicity
(I) Sea ice

(2) Other phenomena, such as tsunamis, submarine slides, seiche, abnormal composition of air and
water, air humidity, salinity, ice drift, icebergs, ice scouring, etc. may require investigation de-
pending upon the specific installation site. The required investigation of seabed and soil con-
ditions is described in Sec 7.

203. Environmental Design Criteria

1. General

The combination and severity of environmental conditions for use in design are to be appropriate to
the installation being considered and consistent with the probability of simultaneous occurrence of
the environmental phenomena. It is to be assumed that environmental phenomena may approach the
installation from any direction unless reliable site-specific data indicate otherwise. The direction, or
combination of directions, which produces the most unfavorable effects on the installation is to be
accounted for in the design.

2. Design Environmental Condition

(1) Design environmental condition is to be described by a set of parameters representing an envi-
ronmental condition which has a high probability of not being exceeded during the life of the
structures and will normally be composed of the followings.
(A) The maximum wave height corresponding to the selected recurrence period together with the
associated wind, current and limits of water depth, and appropriate ice and snow effects.
(B) The extreme air and sea temperatures
(C) The maximum and minimum water level due to tide and storm surge
(2) However, depending upon site-specific conditions, consideration should be given to the combinations of events contained in item (A) above.
(3) The recurrence period chosen for events (1), (A) to (C) above is normally not to be less than one hundred years, unless justification for a reduction can be provided. For platforms that are unmaned, or can be easily evacuated during the design event, or platforms with shorter design life than the typical 20 years may use a recurrence interval less that 100 years for events (1), (A) to (C) above. However, the recurrence interval is not to be less than 50 years.
(4) For installations located in seismically active areas (see 204.8), the magnitudes of the parameters characterizing these earthquakes having recurrence periods appropriate to the design life of the structure are to be determined. The effects of the earthquakes are to be accounted for in design but, generally, need not be taken in combination with other environmental factors.
(5) For installations located in areas susceptible to tsunami waves, submarine slides, seiche or other phenomena, the effects of such phenomena are to be based on the most reliable estimates available and, as practicable, the expected effects are to be accounted for in design.

3. Operating Environmental Conditions

For each intended major function or operation of the installation, a set of characteristic parameters for the environmental factors which act as a limit on the safe performance of an operation or function is to be determined. Such operations may include, as appropriate, transportation, offloading and installation of the structure, drilling or producing operations, evacuation of the platform, etc. These sets of conditions are herein referred to as Operating Environmental Conditions.

204. Specific Environmental Condition

1. Waves

(1) General
Statistical wave data from which design parameters are determined are normally to include the frequency of occurrence of various wave height groups, associated wave periods and directions. Published data and previously established design criteria for particular areas may be used where such exist. Analytical wave spectra employed to augment available data are to reflect the shape and width of the data, and they are to be appropriate to the general site conditions.

(2) Long-Term Predictions
All long-term and extreme-value predictions employed for the determination of design wave conditions are to be fully described and based on recognized techniques. Design wave conditions may be formulated for use in either deterministic or probabilistic methods of analysis, but the method of analysis is to be appropriate to the specific topic being considered.

(3) Data
(A) The development of wave data to be used in required analysis is to reflect conditions at the installation site and the type of structure. As required, wave data may have to be developed to determine the followings.
(a) Provision for air gap
(b) Maximum mud line shear force and overturning moment
(c) Dynamic response of the structure
(d) Maximum stress, fatigue, impact of local structure
(B) Breaking wave criteria are to be appropriate to the installation site and based on recognized techniques. Waves which cause the most unfavorable effects on the overall structure may differ from waves having the most severe effects on individual structural components. In general, more frequent waves of lesser heights, in addition to the most severe wave conditions, are to be investigated when fatigue and dynamic analyses are required.

2. Wind

(1) General
Statistical wind data is normally to include information on the frequency of occurrence, duration and direction of various wind speeds. Published data and data from nearby land and sea stations may be used if available. If on-site measurements are taken, the duration of individual measurements and the height above sea-level of measuring devices is to be stated. Sustained winds are to be considered as those having durations equal to or greater than one minute, while gust winds are winds of less than one minute duration.
(2) Long-Term and Extreme-Value Predictions

Long-term and extreme-value predictions for sustained and gust winds are to be based on recognized techniques and clearly described. Preferably, the statistical data used for the long-term distributions of wind speed should be based on the same averaging periods of wind speeds as are used for the determination of loads. Vertical profiles of horizontal wind are to be determined on the basis of recognized statistical or mathematical models.

(3) Vertical Profiles of Horizontal Wind

Vertical profiles of horizontal wind for use in design can be determined using the following equation.

\[
V_y = V_H \left( \frac{y}{H} \right)^{1/n}
\]

where,
- \( V_y \): wind speed at height \( y \) above a reference water depth (m/sec)
- \( V_H \): wind speed at reference height \( H \), usually 10 m above a reference water depth (m/sec)
- \( 1/n \): exponent dependent upon the time-averaging period of the measured wind speed \( V_H \)
- \( n \): the value of \( n \) typically ranges from 7 for sustained winds to 13 for gust winds of brief duration. For sustained winds of 1 minute duration, \( n \) equal to 7 may be used; for gust winds of 3 second duration, \( n \) equal to 12 may be used.

(4) Time-averaging Data

In the event that wind speed data is not available for the time-averaging period desired for use in design, conversions to the desired time-averaging periods may be made on the basis of Table 3.1.1.

| Table 3.1.1 Wind Speed for Time-Averaging Period \( t \) |
|-----------------|----------------|----------------|----------------|----------------|----------------|
| \( t \) | 1 hr. | 10 min. | 1 min. | 15 sec. | 5 sec. | 3 sec. |
| factor | 1.00 | 1.04 | 1.16 | 1.26 | 1.32 | 1.35 |

Linear interpolation may be used with the Table 3.1.1 to determine the factor to be applied to the time-averaging period wind speed relative to the 1 hour wind speed. For wind speeds given in terms of the "fastest meter of wind", \( V_f \), the corresponding time-averaging period \( t \) in second is given by Table 3.1.1.

\[
t = \frac{8054}{V_f}
\]

where,
- \( V_f \): The fastest meter of wind at a reference height of 10 m (m/sec)
3. Currents

(1) General
Data for currents are generally to include information on current speed, direction and variation with depth. The extent of information needed is to be commensurate with the expected severity of current conditions at the site in relation to other load causing phenomena, past experience in adjacent or analogous area and the type of structure and foundation to be installed. On-site data collection may be indicated for previously unstudied area and/or area expected to have unusual or severe conditions. Consideration is to be given to the following types of currents, as appropriate to the installation site: tidal, wind-generated, density, circulation and river-outflow.

(2) Velocity Profiles
Current velocity profiles are to be based on site-specific data or recognized empirical relationships. Unusual profiles due to bottom currents and stratified effects due to river outflow currents are to be accounted for.

4. Tides

(1) General
Tides, when relevant, are to be considered in the design of an offshore fixed structure. Tides may be classified as lunar or astronomical tides, wind tides, and pressure differential tides. The combination of the latter two is commonly called the storm surge.

(2) The water depth at any location consists of the mean depth, defined as the vertical distance between the sea bed and an appropriate near-surface datum, and a fluctuating component due to astronomical tides and storm surges.

(3) Astronomical tide variations are bounded by highest astronomical tide, HAT, and lowest astronomical tide, LAT, still water level(SWL) should be taken as the sum of the highest astronomical level plus the storm surge.

(4) Storm surge is to be estimated from available statistics or by mathematical storm surge modeling.

(5) Design Environmental Wave Crest
For design purposes, the design environmental wave crest elevation is to be superimposed on the SWL. Variations in the elevation of the daily tide may be used in determining the elevations of boat landings, barge fenders and the corrosion prevention treatment of structure in the splash zone. Water depth assumed for various topics of analysis are to be clearly stated.

5. Temperature

Extreme values of air, sea and seabed temperatures are to be expressed in terms of recurrence periods and associated highest and lowest values. Temperature data is to be used to evaluate selection of structural materials, ambient ranges and conditions for machinery and equipment design, and for determination of thermal stresses, as relevant to the installation.

6. Ice and snow

(1) For structures intended to be installed in areas where ice and snow may accumulate or where sea ice hazards may develop, estimates are to be made of the extent to which ice and snow may accumulate on the structure.

(2) Data may be derived from actual field measurements, laboratory data or data from analogous areas.

7. Marine Growth

(1) Marine growth is to be considered in the design of an offshore installation. Estimates of the rate and extent of marine growth may be based on past experience and available field data.

(2) Particular attention is to be paid to increases in hydrodynamic loading due to increased diameters and surface roughness of members caused by marine fouling as well as to the added weight and increased inertial mass of submerged structural members.

(3) Consideration should be given to the types of fouling likely to occur and their possible effects on corrosion protection coatings.

8. Seismicity and Earthquake Related Phenomena

(1) Effects on Structures
The effects of earthquakes on structures located in areas known to be seismically active are to be taken into account. The anticipated seismicity of an area is, to the extent practicable, to be established on the basis of regional and site specific data including, as appropriate, the...
following.
(A) Magnitudes and recurrence intervals of seismic events
(B) Proximity to active faults
(C) Type of faulting
(D) Attenuation of ground motion between the faults and the site
(E) Subsurface soil conditions
(F) Records from past seismic events at the site where available, or from analogous sites

2) Ground Motion
The seismic data are to be used to establish a quantitative strength level and ductility level earthquake criteria describing the earthquake induced ground motion expected during the life of the structure. In addition to ground motion, and as applicable to the site in question, the following earthquake related phenomena should be taken into account.
(A) Liquefaction of subsurface soils
(B) Submarine slide
(C) Tsunamis
(D) Acoustic overpressure shock waves

9. Sea Ice
(1) The effects of sea ice on structures must consider the frozen-in condition (winter), break-out in the spring, and summer pack ice invasion as applicable.
(2) Impact, both centric and eccentric, must be considered where moving ice may impact a structure. Impact should consider both that of large masses (multi-year floes and icebergs) moving under the action of current, wind, and Coriolis effect, and that of smaller ice masses which are accelerated by storm waves.
(3) The interaction between ice and the structure produces responses both in the ice and the structure-soil system, and this compliance should be taken into account as applicable.
(4) The mode of ice failure (tension, compression, shear, etc.) depends on the shape and roughness of the surface and the presence of adfrozen ice, as well as the ice character, crystallization, temperature, salinity, strain rate and contact area. The force exerted by the broken or crushed ice in moving past the structure must be considered. Limiting force concepts may be employed if thoroughly justified by calculation.

Section 3 Loads

301. General

1. General
This Chapter pertains to the identification, definition and determination of the loads to which an offshore structure may be subjected during and after its transportation to site and its installation. As appropriate to the planned structure, the types of loads described in 302. are to be accounted for in design.

302. Types of Loads

1. General
Loads applied to an offshore structure are, for purposes of these Rules, categorized as follows.

2. Dead Load
Dead loads are loads which do not change during the mode of operation under consideration. Dead loads include the following.
(A) Weight in air of the structure including, as appropriate, the weight of the principal structure (e.g., jacket, tower, caissons, gravity foundation, piling), grout, module support frame, decks, modules, stiffeners, piping, helideck, skirt, columns and any other fixed structural parts.
(B) Weight of permanent ballast and the weight of permanent machinery
(C) External hydrostatic pressure and buoyancy calculated on the basis of the still water level
(D) Static earth pressure
3. Live Load

(1) Live loads associated with the normal operation and use of the structure are loads which may change during the mode of operation considered. (Though environmental loads are live loads, they are categorized separately; see Par 5) Live loads acting after construction and installation include the following.

(A) The weight of drilling or production equipment which can be removed, such as derrick, draw works, mud pumps, mud tanks, rotating equipment, etc.
(B) The weight of crew and consumable supplies, such as mud, chemicals, water, fuel, pipe, cable, stores, drill stem, casting, etc.
(C) Liquid in the vessels and pipes during operation and testing
(D) The weight of liquids in storage and ballast tanks
(E) The forces exerted on the structure due to operations, e.g., maximum derrick reaction
(F) The forces exerted on the structure during the operation of cranes and vehicles
(G) The forces exerted on the structure by vessels moored to the structure or accidental impact consideration for a typical supply vessel that would normally service the installation
(H) The forces exerted on the structure by helicopters during take-off and landing, or while parked on the structure

(2) Where applicable, the dynamic effects on the structure of items (1) (E) through (H) are to be taken into account. Where appropriate, some of the items of live load listed above may be adequately accounted for by designing decks, etc. to a maximum, uniform area load as specified by the Operator, or past practice for similar conditions. Live loads occurring during transportation and installation are to be determined for each specific operation involved and the dynamic effects of such loads are to be accounted for as necessary. (see Sec 9)

4. Deformation Loads

Deformation loads are loads due to deformations imposed on the structure. The deformation loads include those due to temperature variations (e.g., hot oil storage) leading to thermal stress in the structure and where necessary, loads due to displacements (e.g., differential settlement or lateral displacement) or due to deformations of adjacent structures. For concrete structures, deformation loads due to prestress, creep, shrinkage and expansion are to be taken into account.

5. Environmental Loads

Environmental loads are loads due to wind, waves, current, ice, snow, earthquake, and other environmental phenomena. The characteristic parameters defining an environmental load are to be appropriate to the installation site and in accordance with the requirements of Sec 2. Operating Environmental Loads are those loads derived from the parameters characterizing Operating Environmental Conditions (see 203. 3). The combination and severity of Design Environmental Loads are to be in accordance with 203. 2. Environmental loads are to be applied to the structure from directions producing the most unfavorable effects on the structure, unless site-specific studies provide evidence in support of a less stringent requirement. Directionality may be taken into account in applying the environmental criteria. Earthquake loads and loads due to accidents or rare occurrence environmental phenomena need not be combined with other environmental loads, unless site specific conditions indicate that such combinations are appropriate.

303. Determination of Environmental Loads

1. General

(1) Model or field test data may be employed to establish environmental loads. Alternatively, environmental loads may be determined using analytical methods compatible with the data established in compliance with Sec 2.

(2) Any recognized load calculation method may be employed provided it has proven sufficiently accurate in practice, and it is shown to be appropriate to the structure's characteristics and site conditions. The calculation methods presented herein are offered as guidance representative of current acceptable methods.

2. Wave Loads

(1) Range of Wave Parameters
A sufficient range of realistic wave periods and wave crest positions relative to the structure are to be investigated to ensure an accurate determination of the maximum wave loads on the
structure. Consideration should be given to other wave induced effects such as wave impact loads, dynamic amplification and fatigue of structural members. The need for analysis of these effects is to be assessed on the basis of the configuration and behavioral characteristics of the structure, the wave climate and past experience.

(2) Determination of Wave Loads
For structures composed of members having diameters which are less than 20% of the wave lengths being considered, semiempirical formulations such as (3) are considered to be an acceptable basis for determining wave loads. For structures composed of members whose diameters are greater than 20% of the wave lengths being considered, or for structural configurations which substantially alter the incident flow field, diffraction forces and the hydrodynamic interaction of structural members are to be accounted for in design.

(3) Load calculation
(A) The hydrodynamic force acting on a cylindrical member, as given by Morison's equation, is expressed as the sum of the force vectors indicated in the following equation.

\[ F = F_D + F_I \]

\( F \) : hydrodynamic force vector per unit length along the member, acting normal to the axis of the member
\( F_D \) : drag force vector per unit length
\( F_I \) : inertia force vector per unit length

(B) The drag force vector for a stationary, rigid member is given by the following formula.

\[ F_D = \left( \frac{\gamma}{2g} \right) D C_D U_n \| U_n \| \]

\( \gamma \) : weight density of water (N/m³)
\( g \) : gravitational acceleration (m/s²)
\( D \) : projected width of the member in the direction of the crossflow component of velocity (in the case of a critical cylinder, \( D \) denotes the diameter), in m
\( C_D \) : drag coefficient (dimensionless)
\( U_n \) : component of the fluid velocity vector normal to the axis of the member, in m/s
\( \| U_n \| \) : absolute value of \( U_n \), in m/s

(C) The inertia force vector for a stationary, rigid member is given by

\[ F_I = \left( \frac{\gamma}{g} \right) \left( \frac{\pi D^2}{4} \right) C_m a_n \]

\( C_m \) : Inertia coefficient based on the displaced mass of fluid per unit length (dimensionless)
\( a_n \) : component of the fluid acceleration vector normal to the axis of the member, m/s²

(D) For compliant structure which exhibit substantial rigid body oscillations due to the wave action, the modified form of Morison's equation given below may be used to determine the hydrodynamic force.
\[
F = F_D + F_I = \left(\frac{g}{2g}\right) D C_D \left(U_{n'} - U_{n}\right) + \left(\frac{\pi D^2}{4}\right) C_m \left(a_{n} + a_{n}'\right)
\]

\( U_{n'}\): component of the velocity vector of the structural member normal to its axis, in m/s

\( C_m \): added mass coefficient, i.e., \( C_m = C_M - 1 \)

\( a_{n} \): component of the acceleration vector of the structural member normal to its axis, in m/s²

(E) For structural shapes other than circular cylinders, the term \( \pi D^2/4 \) in the above equation is to be replaced by the actual cross-sectional area of the shape.

(F) Values of \( U_{n} \) and \( a_{n} \) for use in Morison's equation are to be determined using a recognized wave theory appropriate to the wave heights, wave periods, and water depth at the installation site. Values for the coefficients of drag and inertia to be used in Morison's equation are to be determined on the basis of model tests, full scale measurements, or previous studies which are appropriate to the structural configuration, surface roughness, and pertinent flow parameters (e.g., Reynolds number). Generally, for pile-supported template type structures, values of \( C_D \) range between 0.6 and 1.2; values of \( C_M \) range between 1.5 and 2.0.

(4) Diffraction Theory
For structural configurations which substantially alter the incident wave field, diffraction theories of wave loading are to be employed which account for both the incident wave force (i.e., Froude-Kylov force) and the force resulting from the diffraction of the incident wave due to the presence of the structure. The hydrodynamic interaction of structural members is to be taken into account. For structures composed of surface piercing caissons or for installation sites where the ratio of water depth to wave length is less than 0.25, nonlinear effects of wave action are to be taken into account. This may be done by modifying linear diffraction theory to account for nonlinear effects or by performance of model tests.

3. Wind Load
(1) Wind loads and local wind pressures are to be determined on the basis of analytical methods or wind tunnel tests on a representative model of the structure.

(2) In general, the wind load on the overall structure to be combined with other design environmental loads is to be determined using a one-minute sustained wind speed. For installations with negligible dynamic response to wind, a one-hour sustained wind speed may be used to calculate the wind loads on the overall structure. Wind loads on broad, essentially flat structures such as living quarters, walls, enclosures, etc. are to be determined using a fifteen-second gust wind speed. Wind pressures on individual structural members, equipment on open decks, etc. are to be determined using a three second gust wind speed.

(3) For wind loads normal to flat surfaces or normal to the axis of members not having flat surfaces, the following relation may be used.

\[
F_w = \left(\frac{\gamma_w}{2g}\right) C_L V_g^2 A
\]

\( F_w \): wind load, in N

\( g \): gravitational acceleration (m/s²)

\( \gamma_w \): weight density of air, in N/m³

\( C_L \): shape coefficient (dimensionless)

\( V_g \): wind speed at altitude \( y \), in m/s

\( A \): projected area of member on a plane normal to the direction of the considered force, in m²
(4) For any direction of wind approach to the structure, the wind force on flat surfaces should be considered to act normal to the surface. The wind force on cylindrical objects should be assumed to act in the direction of the wind.

(5) The area of open trussworks commonly used for derricks and crane booms may be approximated by taking 30% of the projected area of both the windward and leeward sides with the shape coefficient taken in accordance with Table 3.3.1.

**Table 3.3.1 Values of shape coefficient \( C_s \)**

<tr>
<td>Derricks or truss cranes(each face)</td>
<td>1.25</td>
</tr>
</tbody>
</table>

(6) Where one structural member shields another from direct exposure to the wind, shielding may be taken into account.

(7) Generally, the two structural components are to be separated by not more that seven times the width of the windward component for a reduction to be taken in the wind load on the leeward member.

(8) Where appropriate, dynamic effect due to the cyclical nature of gust wind and cyclic loads due to vortex induced vibration are to be investigated. Both drag and lift components of load due to vortex induced vibration are to be taken into account.

(9) The effects of wind loading on structural members or components that would not normally be exposed to wind loads after platform installation are to be considered. This would especially apply to fabrication or transportation phases.

## 4. Current Loads

(1) Current induced loads on immersed structural members are to be determined on the basis of analytical methods, model test data or full-scale measurements.

(2) When currents and waves are superimposed, the current velocity is to be added vectorially to the wave induced particle velocity prior to computation of the total force.

(3) Current profiles used in design are to be representative of the expected conditions at the installation site.

(4) Where appropriate, flutter and dynamic amplification due to vortex shedding are to be taken into account.

(5) For calculation of current loads in the absence of waves, the lift force normal to flow direction, and the drag force may be determined as follows.

\[
F_L = C_L \left( \frac{\gamma}{2g} \right) V^2 A_1, \quad F_D = C_D \left( \frac{\gamma}{2g} \right) V^2 A_1
\]

- \( F_L \): total lift force per unit length, in N/m
- \( C_L \): lift coefficient (dimensionless)
- \( \gamma \): weight density of water, in N/m³
- \( V \): local current velocity, in m/s
- \( A_1 \): projected area per unit length in a plane normal to the direction of the force, in m²/m
- \( F_D \): total drag force per unit length, in N/m
- \( C_D \): drag coefficient
(6) In general, lift force may become significant for long cylindrical members with large length-diameter ratios and should be checked in design under these conditions. The source of $C_L$ values employed is to be documented.

5. Ice and Snow Loads

(1) At locations where structures are subject to ice and snow accumulation the following effects are to be accounted for, as appropriate to the local conditions.
   (A) Weight and change in effective area of structural members due to accumulated ice and snow
   (B) Incident pressures due to pack ice, pressure ridges and ice island fragments impinging on the structure

(2) For the design of structures that are to be installed in service in extreme cold weather such as arctic regions, reference is to be made to API 2N: "Planning, Designing, and Constructing Fixed Offshore Platforms in Ice Environments"

6. Earthquake Loads

(1) For structures located in seismically active areas strength level and ductility level earthquake induced ground motions are to be determined on the basis of seismic data applicable to the installation site.

(2) Earthquake ground motions are to be described by either applicable ground motion records or response spectra consistent with the recurrence period appropriate to the design life of the structure.

(3) Available standardized spectra applicable to the region of the installation site are acceptable provided such spectra reflect site-specific conditions affecting frequency content, energy distribution, and duration. These condition include: the type of active faults in the region, the proximity of the site to the potential source faults, the attenuation or amplification of ground motion between the faults and the site, and the soil conditions at the site.

(4) The ground motion description used in design is to consist of three components corresponding to two orthogonal horizontal directions and the vertical direction. All three components are to be applied to the structure simultaneously. When a standardized response spectrum, such as given in the American Petroleum Institute (API) RP 2A, is used for structural analysis, input values of ground motion (spectral acceleration representation) to be used are not to be less severe than the following.
   (A) 100% in both orthogonal horizontal directions
   (B) 50% in the vertical direction.

(5) When three-dimensional, site-specific ground motion spectra are developed, the actual directional accelerations are to be used.

(6) When three-dimensional, site-specific ground motion spectra are developed, the actual directional accelerations are to be used. If single site-specific spectra are developed, accelerations for the remaining two orthogonal directions should be applied in accordance with the factors given above.

(7) If time history method is used for structural analysis, at least three sets of ground motion time histories are to be employed. The manner in which the time histories are used is to account for the potential sensitivity of the structure's response to variations in the phasing of the ground motion records. Structural appurtenances, equipment, modules, and piping are to be designed to resist earthquake induced accelerations at their foundations. As appropriate, effects of soil liquefaction, shear failure of soft muds and loads due to acceleration of the hydrodynamic added mass by the earthquake, submarine slide, tsunamis and earthquake generated acoustic shock waves are to be taken into account.

7. Marine Growth

(1) The following effects of anticipated marine growth are to be accounted for in design.
   (A) Increase in hydrodynamic diameter
   (B) Increase in surface roughness in connection with the determination of hydrodynamic coefficients (e.g., lift, drag and inertia coefficients)
   (C) Increase in dead load and inertial mass

(2) The amount of accumulation assumed for design is to reflect the extent of and interval between cleaning of submerged structural parts.
8. Sea Ice

(1) The global forces exerted by sea ice on the structure as a whole and local concentrated loads on structural elements are to be considered. The effects of rubble piles on the development of larger areas, and their forces on the structure, need to be considered.

(2) The impact effect of a sea ice feature must consider mass and hydrodynamic added mass of the ice, its velocity, direction and shape relative to the structure, the mass and size of the structure, the added mass of water and soil accelerating with the structure, the compliance of the structure-soil interaction and the failure mode of the ice-structure interaction.

(3) The dynamic response of structure to ice may be important in flexible structures.

(4) As appropriate, liquefaction of the underlying soils due to repetitive compressive failures of the ice against the structure is to be taken into account.

9. Subsidence

The effects of subsidence should be considered in the overall foundation and structural design. This would be especially applicable to facilities where unique geotechnical conditions exist such that significant sea floor subsidence could be expected to occur as a result of depletion of the subsurface reservoir.

Section 4 General Design Requirements

401. General

1. General

This section of the Rules outlines general concepts and considerations which may be incorporated in design. In addition, considerations for particular types of offshore structures are enumerated.

402. Analytical Approaches

1. Format of Design Specifications

The design requirements of these Rules are generally specified in terms of a working stress format for steel structures and an ultimate strength format for concrete structures. In addition, the Rules require that consideration be given to the serviceability of structure relative to excessive deflection, vibration, and, in the case of concrete, cracking. The Society will give special consideration to the use of alternative specification formats, such as those based on probabilistic or semiprobabilistic limit state design concepts.

2. Loading Formats

(1) With reference Sec 2 and Sec 3, either a deterministic or spectral format may be employed to describe various load components.

(2) When a static approach is used, it is to be demonstrated, where relevant, that consideration has been given to the general effects of dynamic amplification.

(3) The influence of waves other than the highest waves is to be investigated for their potential to produce maximum peak stresses due to resonance with the structure.

(4) When considering an earthquake in seismically active areas (see Sec 3), a dynamic analysis is to be performed. A dynamic analysis is also to be considered to assess the effects of environmental or other types of loads where dynamic amplification is expected.

(5) When a fatigue analysis is performed, a long-term distribution of the stress range, with proper consideration of dynamic effects, is to be obtained for relevant loadings anticipated during the design life of the structure. (see 506. 2, 603. 4)

(6) If the modal method is employed in dynamic analysis, it should be recognized that the number of modes to be considered is dependent on the characteristics of the structure and the conditions being considered.

(7) For earthquake analysis, a minimum number of modes is to be considered to provide approximately 90% of the total energy of all modes.

(8) The correlation between the individual modal responses in determining the total responses is to be investigated. The complete quadratic combination (CQC) method may be used when the combining modal responses is small, the total response may be calculated as the square root of the
sum of the squares of the individual modal responses.

(9) For extreme wave and fatigue analyses, dynamic response is to be considered for structural modes having periods greater than 3.0 seconds. For significant modes with periods of 3.0 seconds or less, the dynamic effect need not be considered provided the full static effect (including flexure of individual members due to localized wave forces) is considered.

3. Combination of Loading Components

(1) Loads imposed during and after installation are to be taken into account.

(2) In consideration of the various loads described in Sec 3, loads to be considered for design are to be combined consistent with their probability of simultaneous occurrence. However, earthquake loadings may be applied without consideration of other environmental effects unless conditions at the site necessitate their inclusion.

(3) If site-specific directional data is not obtained, the direction of applied environmental loads is to be such as to produce the highest possible influence on the structure. Loading combinations corresponding to conditions after installation are to reflect both operating and design environmental loadings. (See 203.)

(4) Reference is to be made to Sec 5, Sec 6, Sec 7, regarding the minimum load combinations to be considered. The operator is to specify the operating environmental conditions and the maximum tolerable environmental loads during installation.

403. Overall Design Considerations

1. Design Life

The design life of the structure is to be specified by the Operator. Continuance of classification beyond the Design Life will be subject to a special survey and engineering analysis.

2. Air Gap

(1) An air gap of at least 1.5 m is to be provided between the maximum wave crest elevation and the lowest protuberance of the superstructure for which wave forces have not been included in the design.

(2) After accounting for the initial and expected long-term settlements of the structure, due to consolidation and subsidence in a hydrocarbon or other reservoir area, the design wave crest elevation is to be superimposed on the still water level and consideration is to be given to eave run-up, tilting of the structure and, where appropriate, tsunamis.

3. Long-term and Secondary Effects

Consideration is to be given to the following effects, as appropriate to the planned structure.

(A) Local vibration due to machinery, equipment and vortex shedding

(B) Stress concentrations at critical joints

(C) Secondary stresses induced by large deflection (P-△ effects)

(D) Cumulative fatigue

(E) Corrosion

(F) Abrasion due to ice

(G) Freeze-thaw action on concrete and coatings

4. Reference Marking

(1) For large or complex structures, consideration should be given to installing permanent reference markings during construction to facilitate future surveys. Where employed, such markings may consist of weld beads, metal or plastic tags, or other permanent markings.

(2) In the case of a concrete structure, markings may be provided using suitable coatings or permanent lines molded into the concrete.

5. Zones of Exposure

(1) Measures taken to mitigate the effects of corrosion as required by 501.3 and 601.3 are to be specified and described in terms of the following definitions for corrosion protection zones.

(A) Submerged Zone: The part of the installation below the splash zone.

(B) Splash Zone: The part of the installation containing the areas above and below the still water level which are regularly subjected to wetting due to wave action. Characteristically, the splash zone is not easily accessible for field painting, nor protected by cathodic protection.
(C) Atmospheric Zone: That part of the installation above the splash zone.
(2) Additionally, for structures located in areas subject to floating or submerged ice, that portion of the structure which may reasonably be expected to come into contact with floating or submerged ice is to be designed with consideration for such contact.

404. Considerations for Particular Types of Structures

1. General
   (1) In this subsection are listed specific design considerations which are to be taken into account for particular types of structures.
   (2) Where required, the interactive effects between the platform and conductor or riser pipes due to platform motions are to be investigated. For compliant structures which exhibit significant wave induced motions, determination of such interactive effects may be of critical importance.

2. Pile-Supported Steel Platforms
   (1) Factors to be considered
       Factors to be considered in the structural analysis are to include the soil-pile interaction and the loads imposed on the tower or jacket during towing and launching.
   (2) Installation Procedures
       Carefully controlled installation procedures are to be developed so that the bearing loads of the tower or jacket on the soil are kept within acceptable limits until the piles are driven.
   (3) Special Procedures
       Special procedures may have to be used to handle long, heavy piles until they are self-supporting in the soil. Pile driving delays are to be minimized to avoid set-up of the pile sections.
   (4) Dynamic Analysis
       For structures likely to be sensitive to dynamic response, the natural period of the structure should be checked to insure that it is not in resonance with eaves having significant energy content.
   (5) Instability
       Instability of structural members due to submersion is to be considered, with due account for second-order effects produced by factors such as geometrical imperfections.

3. Concrete or Steel Gravity Platforms
   (1) Positioning
       The procedure for transporting and positioning the structure and the accuracy of measuring devices used during these procedures are to be documented.
   (2) Repeated Loadings
       Effects of repeated loadings on soil properties, such as pore pressure, water content, shear strength and stress strain behavior, are to be investigated.
   (3) Soil Reactions
       Soil reactions against the base of the structure during installation are to be investigated. Consideration should be given to the occurrence of point loading caused by sea bottom irregularities. Suitable grouting between base slab and sea floor can be employed to reduce concentration of loads.
   (4) Maintenance
       The strength and durability of construction materials are to be maintained. Where sulphate attack is anticipated, as from stored oil, appropriate cements are to be chosen, pozzolans incorporated in the mix, or the surfaces given suitable coatings.
   (5) Reinforcement Corrosion
       Means are to be provided to minimize reinforcing steel corrosion.
   (6) Instability
       Instability of structural members due to submersion is to be considered, with due account for second-order effects produced by factors such as geometrical imperfections.
   (7) Horizontal sliding
       Where necessary, protection against horizontal sliding along the sea floor is to be provided by means of skirts, shear keys or an equivalent means.
   (8) Dynamic Analysis
       A dynamic analysis, including simulation of wave-structure response and soil-structure interaction, should be considered for structures with natural periods greater than approximately 3 seconds.
(9) Long Term Resistance
   The long term resistance to abrasion, cavitation, freeze-thaw durability and strength retention of
   the concrete are to be considered.

(10) Negative Buoyancy
   Provision is to be made to maintain adequate negative buoyancy at all times to resist the uplift
   forces from waves, currents, and overturning moments. Where this is achieved by ballasting oil
   storage tanks with sea water, continuously operating control devices should be used to maintain
   the necessary level of the oil-water interface in the tanks.

4. Concrete–Steel Hybrid Structures
   (1) Horizontal Loading
      Where necessary, the underside of the concrete base is to be provided with skirts or shear keys
      to resist horizontal loading; steel or concrete keys or an equivalent means may be used.

   (2) Steel and Concrete Interfaces
      Special attention is to be paid to the design of the connections between steel and concrete
      components.

   (3) Other Factors
      Pertinent design factors for the concrete base listed in Par 3 are also to be taken into account.

5. Minimum structure
   (1) These Rules are to be applied in design of minimum structures wherever applicable. Minimum
       structures generally have less structural redundancy and more prominent dynamic responses due
       to the flexible nature of the structural configuration.

   (2) Dynamic effects on the structure are to be considered in the structural analysis when the struc-
       ture has a natural period greater than 3 seconds. The pertinent design factors listed Par 2 are
       to be taken into account.

   (3) Connections other than welded joints are commonly used in minimum structures. For these me-
       chanical connections such as clamps, connectors and bolts, joining diagonal braces to the col-
       umn or piles to the minimum structure, the strength and fatigue resistance are to be assessed by
       analytical methods or testing.

6. Site Specific Self-Elevating Mobile Offshore Units
   (1) Self-Elevating Mobile Offshore Units converted to site dependent platform structures are to be
       designed in accordance with these Rules along with the Rules for Classification Mobile
       Offshore Units, wherever applicable.

   (2) When selecting a unit for a particular site, due consideration should be given to soil conditions
       at the installation site.

   (3) The bearing capacity and sliding resistance of the foundation are to be investigated. The founda-
       tion design is to be in accordance with 705.

   (4) Structural Analysis
      (A) In the structural analysis, the leg to hull connections and soil/structure interaction are to be
          properly considered.

      (B) The upper and lower guide flexibility, stiffness of the elevating/holding system, and any spe-
          cial details regarding its interaction with the leg should be taken into consideration. For
          units with spud cans, the leg may be assumed pinned at the reaction point.

      (C) For mat supported units, the soil structure interaction may be modelled using springs.

   (5) While used as a site dependent platform structure, the calculated loads are to demonstrate that
       the maximum holding capacity of the jacking system will not be exceeded.

   (6) Units with spud cans are to be preloaded on installation in order to minimize the possibility of
       significant settlement under severe storm conditions.

Section 5 Steel Structures

501. General

1. General
   (1) The requirements of this Chapter are to be applied in the design and analysis of the principal
       components of steel structures intended for offshore applications.

   (2) Items to be considered in the design of welded connections are specified in Ch 3, Sec 2.
2. Materials
(1) The requirements of this Chapter are intended for structures constructed of steel manufactured and having properties as specified in Ch 3, Sec 1.
(2) Where it is intended to use steel or other materials having properties differing from those specified in Ch 3, Sec 1, their applicability will be considered subject to a review of the specifications for the alternative materials and the proposed methods of fabrication.

3. Corrosion Protection
(1) Materials are to be protected from the effects of corrosion by the use of a corrosion protection system including the use of coatings. The system is to be effective from the time the structures is initially placed on site.
(2) Where the sea environment contains unusual contaminants, any special corrosive effects of such contaminants are also to be considered. (For the design of protection systems, reference is to be made to the NACE SP0176-2007, or other appropriate references)
(3) The design of corrosion protecting device is to be accordance with the discretion of this Society.

4. Access for Inspection
In the design of the structure, consideration should be given to providing access for inspection during construction and, to the extent practicable, for survey after construction.

5. Steel–Concrete Hybrid Structures
The steel portion of steel-concrete hybrid structures are to be designed in accordance with the requirements of this Chapter, and the concrete portions are to be designed as specified in Ch 4, Sec 6.

502. General Design Criteria

1. Application
(1) Steel structures are to be designed and analyzed for the loads to which they are likely to be exposed during construction, installation and in-service operations.
(2) To this end, the effects on the structure of a minimum set of loading conditions, as indicated in 503, are to be determined, and the resulting structural responses are not to exceed the safety and serviceability criteria given below.
   (A) The use of design methods and associated safety and serviceability criteria, other than those specifically covered in this Chapter, is permitted where it can be demonstrated that the use of such alternative methods will result in a structure possessing a level of safety equivalent to that provided by the direct application of these requirements.

503. Loading Conditions

1. General
(1) Loadings which produce the most unfavorable effects on the structure during and after construction and installation are to be considered.
(2) Loadings to be investigated for conditions after installation are to include at least those relating to both the realistic operating and design environmental conditions combined with other pertinent loads in the following manner.
   (A) Operating environmental loading combined with dead and maximum live loads appropriate to the function and operations of the structures.
   (B) Design environmental loading combined with dead and live loads appropriate to the function and operations of the structure during the design environmental condition.
   (C) For structures located in seismically active areas, earthquake loads (see 303.6) are to be combined with dead and live loads appropriate to the operation and function of the structure which may be occurring at the onset of an earthquake.
504. Structural Analysis

1. Application

(1) The nature of loads and loading combinations as well as the local environmental conditions are to be taken into consideration in the selection of design methods. Methods of analysis and their associated assumptions are to be compatible with the overall design principles.

(2) Linear, elastic methods (working stress methods) can be employed in design and analysis provided proper measures are taken to prevent general and local buckling failure, and the interaction between soil and structure is adequately treated.

(3) When assessing structural instability as a possible mode of failure, the effects of initial stresses and geometric imperfections are to be taken into account.

(4) Construction tolerances are to be consistent with those used in the structural stability assessment.

2. Dynamic analysis

(1) Dynamic effects are to be accounted for if the wave energy in the frequency range of the structural natural frequencies is of sufficient magnitude to produce significant dynamic response in the structure.

(2) In assessing the need for dynamic analyses of deep water or unique structures, information regarding the natural frequencies of the structure in its intended position is to be obtained.

(3) The determination of dynamic effects is to be accomplished either by computing the dynamic amplification effects in conjunction with a deterministic analysis or by a random dynamic analysis based on a probabilistic formulation. In the latter case, the analysis is to be accompanied by a statistical description and evaluation of the relevant input parameters.

3. Plastic methods of Design

(1) For static loads, plastic methods of design and analysis can be employed only when the properties of the steel and the connections are such that they exclude the possibility of brittle fracture, allow for formation of plastic hinges with sufficient plastic rotational capability, and provide adequate fatigue resistance.

(2) In a plastic analysis, it is to be demonstrated that the collapse mode (mechanism) which corresponds to the smallest loading intensities has been used for the determination of the ultimate strength of the structure. Buckling and other destabilizing nonlinear effects are to be taken into account in the plastic analysis.

(3) Whenever non-monotonic or repeating loads are present, it is to be demonstrated that the structure will not fail by incremental collapse or fatigue.

(4) Under dynamic loads, when plastic strains may occur, the considerations specified in (1) are to be satisfied and any buckling and destabilizing nonlinear effects are to be taken into account.

505. Allowable Stresses and Load Factors

1. Working Stress Approach

When design is based on a working stress method (see 504.1 and 402.), the safety criteria are to be expressed in terms of appropriate basic allowable stresses in accordance with requirements specified below.

(A) Structural members and loadings are to be in accordance with the discretion of this Society.

(B) Where stress in members is due to forces imposed by the design environmental condition acting alone or in combination with dead and live loads the basic allowable stresses may be increased by one-third provided the resulting structural member sizes are not less than those required for the operating environment loading combined with dead and live loads without the one-third increase in allowable stresses.

(C) When considering loading combinations which include earthquake loads (see 503.) on individual members or on the overall structure, the allowable stress may be taken 1.7 times the basic allowable stress of the member.

(D) The allowable stresses specified in (B) are to be regarded as the limits for stresses in all structural parts for the marine operations covered in Sec 9., except for lifting, where the one third increase in the basic allowable stress is not permitted. The lifting analysis should adequately account for equipment and fabrication weight increase.

(E) For any two or three dimensional stress field within the scope of the working stress formulation, the equivalent stress (e.g., von Mises stress intensity) is to be limited by an appropriate allowable stress less than yield stress, with the exception of those stresses of a highly
localized nature, In the latter case, local yielding of the structure may be accepted provided it can be demonstrated that such yielding does not lead to progressive collapse of the overall structure and that the general structural stability is maintained.

(F) Whenever elastic instability, overall or local, may occur before the stresses reach their basic allowable levels, appropriate allowable buckling stresses govern.

2. Plastic Design Approach

(1) Whenever the ultimate strength of the structure is used as the basis for the design of its members, the safety factors or the factored loads are to be formulated in accordance with the requirements of this Society or an equivalent code.

(2) The capability of the principle structural members to develop their predicted ultimate load capacity is to be demonstrated.

(3) For safety against brittle fracture, special attention is to be given to details of high stress concentration and to improved material quality.

506. Others

1. Structural Response to Earthquake Loads

(1) Structures located in seismically active areas are to be designed to possess adequate strength and stiffness to withstand the effects of strength level earthquake, as well as sufficient ductility to remain stable during rare motions of greater severity associated with ductility level earthquake. The sufficiency of the structural strength and ductility is to be demonstrated by strength and, as required, ductility analysis.

(2) For strength level earthquake, the strength analysis is to demonstrate that the structure is adequately sized for strength and stiffness to maintain all nominal stresses within their yield or buckling limits.

(3) In the ductility analysis, it is to be demonstrated that the structure has the capability of absorbing the energy associated with the ductility level earthquake without reaching a state of incremental collapse.

(4) The design criteria for earthquake is to be in accordance with the discretion of this Society.

2. Fatigue Assessment

(1) For structural members and joints where fatigue is a probable mode of failure, or for which past experience is insufficient to assure safety from possible cumulative fatigue damage, an assessment of fatigue life is to be carried out. Emphasis is to be given to joints and members in the splash zone, those that are difficult to inspect and repair once the structure is in service, and those susceptible to corrosion-accelerated fatigue.

(2) For structural members and joints which require a detailed assessment of cumulative fatigue damage, the results of the assessment are to indicate a minimum expected fatigue life of twice the design life of the structure where sufficient structural redundancy exists to prevent catastrophic failure of the structure of the member or joint under consideration. Where such redundancy does not exist or where the desirable degree of redundancy is significantly reduced as a result of fatigue damage, the result of a fatigue assessment is to indicate a minimum expected fatigue life of three or more times the design life of the structure.

(3) A spectral fatigue analysis technique is recommended to calculate the fatigue life of the structure. Other rational analysis methods are also acceptable if the forces and member stresses can be properly represented. The dynamic effects should be taken into consideration if they are significant to the structural response.

3. Stresses in Connections

(1) Connections of structural members are to be developed to insure effective load transmission between joined members, to minimize stress concentration and to prevent excessive punching shear.

(2) Connection details are also to be designed to minimize undue constraints against overall ductile behavior and to minimize the effects of postweld shrinkage. Undue concentration of welding is to be avoided.

(3) The design of tubular joints may be in accordance the discretion of this Society.
4. Structure–Pile Connections

(1) The attachment of the structure to its foundation is to be accomplished by positive, controlled means such as welding or grouting, with or without the use of mechanical shear keys or other mechanical connectors.

(2) General references may be made to the discretion of this Society where the ratio of the diameter to thickness of either the pile or the sleeve is less than or equal to 80. Where a ratio exceeds 80, special consideration is to be given to the effects of reduced confinement on allowable bond stress. Particulars of grouting mixtures are to be submitted for review.

(3) The allowable stresses or load factors to be employed in the design of foundation structure for steel gravity bases or piles are to be in accordance with 505.1 or 2, and with regard to laterally loaded piles in accordance with 704. 5.

5. Structural Response to Hydrostatic Loads

Analyses of the structural stability are to be performed to demonstrate the ability of structural parts to withstand hydrostatic collapse at the water depths at which they will be located.

6. Deflections

The platform deflections which may affect the design of piles, conductors, risers and other structures in way of the platform are to be considered. Where appropriate, the associated geometric non-linearity is to be accounted for in analysis.

7. Local Structure

(1) Structures which do not directly contribute to the overall strength of the fixed offshore structure, i.e., their loss or damage would not impair the structural integrity of the offshore structure, are considered to be local structure.

(2) Local structures are to be adequate for the nature and magnitude of applied loads. Allowable stresses specified in 505. are to be used as stress limits except for those structural parts whose primary function is to absorb energy, in which case sufficient ductility is to be demonstrated.

Section 6 Concrete Structure

601. General

1. Application

The requirements of this Chapter are to be applied to offshore installations of reinforced and pre-stressed concrete construction.

2. Materials

(1) Unless otherwise specified, the requirements of this Chapter are intended for structures constructed of materials manufactured and having properties as specified in Ch 3.

(2) Where it is intended to use materials having properties differing from those specified in Ch 3, the use of such materials will be specially considered. Specifications for alternative materials, details of the proposed methods of manufacture and, where available, evidence of satisfactory previous performance, are to be submitted for approval.

3. Durability

(1) Materials, concrete mix proportions, construction procedures and quality control are to be chosen to produce satisfactory durability for structures located in a marine environment.

(2) Problems to be specifically addressed include chemical deterioration of concrete, corrosion of the reinforcement and hardware, abrasion of the concrete, freeze-thaw durability, and fire hazards as they pertain to the zones of exposure defined in 403. 5.

(3) Test mixes should be prepared and tested early in the design phase to ensure that proper values of strength, creep, alkali resistance, etc. will be achieved.

4. Access for Inspection

The components of the structure are to be designed to enable their inspection during construction and, to the extent practicable, periodic survey after installation.
5. Steel–Concrete Hybrid Structures

The concrete portions of a hybrid structure are to be designed in accordance with the requirements of this Chapter, and the steel portions in accordance with the requirements of Sec 5.

602. General Design Criteria

1. Design Method

(1) The requirements of this Section relate to the ultimate strength method of design.

(2) Load magnitude

The magnitude of a design load for given type of loading is obtained by multiplying the load, F, by the appropriate load factor r, i.e., design load = r \cdot F

(3) Design Strength

In the analysis of sections, the design strength of a given material is obtained by multiplying the material strength, f, by the appropriate strength reduction factor \( \psi \) (i.e., design strength = \( \psi \cdot f \)). The material strength f, for concrete is the specified compression strength of concrete after 28 days and for steel is the minimum specified yield strength.

2. Load Definition

(1) Load Categories

The load categories referred to in this section, i.e., dead loads, live loads, deformation loads, and environmental loads, are defined in 302.

(2) Combination Loads

Loads taken in combination for the Operating Environmental Conditions and the Design Environmental Condition are indicated in 603. 2.

(3) Earthquake and Other Loads

Earthquake loads and loads due to environmental phenomena of rare occurrence need not be combined with other environmental loads unless site-specific conditions indicate that such combination is appropriate.

3. Design Reference

Design considerations for concrete structures not directly addressed in these Rules are to be in accordance with discretion of this Society. (ex.: ACI 318, ACI 357 or an equivalent recognized standard.)

603. Design Requirements

1. General

(1) The strength of the structure is to be such that adequate safety exists against failure of the structure or its components. Among the modes of possible failure to be considered are the following.

(A) Loss of overall equilibrium

(B) Failure of critical sections

(C) Instability (buckling)

(2) The serviceability of the structure is to be assessed. The following items are to be considered in relation to their potential influences on the serviceability of the structure.

(A) Cracking and spalling

(B) Deformations

(C) Corrosion of reinforcement of deterioration of concrete

(D) Vibrations

2. Required Strength

(1) The required strength \( U \) of the structure and each member is to be equal to, or greater than, the maximum of the following.

\[
U = 1.2(D + T) + 1.6L_{\text{max}} + 1.3E_0 \\
U = 1.2(D + T) + 1.2L_{\text{max}} + r_K E_{\text{max}} \\
U = 0.9(D + T) + 0.9L_{\text{min}} + r_K E_{\text{max}}
\]
in which \( r_E \) assumes the following values:

- for wave, current, wind, or ice load: \( r_E = 1.3 \)
- for earthquake loads: \( r_E = 1.4 \)

In the preceding relations, the symbols \( D, T, \) and \( L \) represent dead load, deformation load, and live load, respectively (see 602.2).

\[ E_0 \text{ : operating environmental loads} \]
\[ E_{\text{max}} \text{ : design environmental loads} \]
\[ L_{\text{min}} \text{ : minimum expected live loads} \]
\[ L_{\text{max}} \text{ : maximum expected live loads} \]

For load of type \( D \): the load factor 1.2 is to be replaced by 1.0 if it leads to a more unfavorable load combination results. For strength evaluation the effects of deformation load may be ignored provided adequate ductility is demonstrated.

(2) While the critical design loadings will be identified from the load combinations given above, the other simultaneously occurring load combinations during construction and installation phases are to be considered if they can cause critical load effects.

3. Strength Reduction Factors

The strength of a member or a cross section is to be calculated in accordance with the provision of 604, and it is to be multiplied by the following strength reduction factor \( \psi \).

(A) For bending with or without axial tension, \( \psi = 0.90 \)
(B) For axial compression or axial compression combined with bending.
   (a) Reinforced members with spiral reinforcement, \( \psi = 0.75 \)
   (b) Other reinforced members (excluding slabs and shells), \( \psi = 0.70 \)
   (c) The values (A) and (B) given above may be increased linearly to 0.9 as \( P_u \) decrease from \( 0.1f' \cdot A_g \) or \( P_h \), whichever is smaller, to zero.

\[ f' \text{ : specified compression strength of concrete} \]
\[ A_g \text{ : gross area of section} \]
\[ P_u \text{ : axial design load in compression member} \]
\[ P_h \text{ : axial load capacity assuming simultaneous occurrence of the ultimate strain of concrete and yielding of tension steel} \]

(d) Slabs and shells \( \psi = 0.70 \)
(C) For shear and torsion, \( \psi = 0.85 \)
(D) For bearing on concrete, \( \psi = 0.70 \)

4. Fatigue

(1) The fatigue strength of the structure will be considered satisfactory if under the unfactored operating loads the following conditions are satisfied.

(A) The stress range in reinforcing or prestressing steel does not exceed 138 N/mm\(^2\), or where reinforcement is bent, welded or spliced 69 N/mm\(^2\)
(B) There is no membrane tensile stress in concrete and not more than 1.4 N/mm\(^2\) flexural tensile stress in concrete.
(C) The stress range in compression in concrete does not exceed 0.5 \( f' \), where \( f' \) is the specified compressive strength of concrete.
(D) Where maximum shear exceeds the allowable shear of the concrete alone, and where the cyclic range is more than half the maximum allowable shear in the concrete alone, all shear is taken by reinforcement. In determining the allowable shear of the concrete alone, the influence of permanent compressive stress may be taken into account.

(E) Bond stress does not exceed 50% of that permitted for static loads.

(2) Where the above nominal values are exceeded, an in-depth fatigue analysis is to be carried out.
For those analysis, reduction of material strength is to be taken into account on the basis of appropriate data (S-N curves) corresponding to the 95th percentile of specimen survival. In this regard, consideration is to be given not only to the effects of fatigue induced by normal stress, but also to fatigue effects due to shear and bond stress. Particular attention is to be given to submerged areas subjected to the lowcycle, high-stress components of the loading history.

(3) Where an analysis of the fatigue life is performed, the expected fatigue life of the structure is to be at least twice the design life. In order to estimate the cumulative fatigue damage under variable amplitude stresses, a recognized cumulative rule is to be used. Miner’s rule is an acceptable method for the cumulative fatigue damage analysis.

5. Serviceability Requirements

(1) Serviceability

(A) The serviceability of the structure is to be checked by the use of stress-strain diagrams (see Fig 3.6.1 and Fig 3.6.2) with strength reduction factor ($\psi = 1.0$), and the unfactored load combination.

$$ U = D + T + L + E_0 $$

Where $L$ is the most unfavorable live load and all other terms are as previously defined (see Par 2).

(B) Using this method as the above (1) the reinforcing stresses are to be limited in compliance with Table 3.6.1. Additionally for hollow structural cross sections, the maximum permissible membrane strain across the wall should not cause cracking under any combination of $D_i$, $T$, $L$ and $E_{max}$ using load factors taken as 1.0.

(C) For structures prestressed in one direction only, tensile stresses in reinforcement transverse to the prestressing steel shall be limited so that the strains at the plane of the prestressing steel do not exceed $\Delta P_s/E_s$. Where $\Delta P_s$ is as defined in Table 3.6.1 and $E_s$ is the modulus of elasticity of reinforcement.

$$ \Delta P_s : \text{defined in Table 3.6.1.} $$

$$ E_s : \text{defined in 604. 2} $$

(D) Alternative criteria such as those which directly limit crack width will also be considered.

(2) Liquid-Containing Structures

The following criteria are to be satisfied for liquid-containing structures to ensure adequate design against leakage.

(A) The reinforcing steel stresses are to be in accordance with Table 3.6.1.

(B) The compression zone is to extend over 25% of the wall thickness or 205 mm, whichever is less.

(C) There is to be no membrane tensile stress unless other construction arrangements are made, such as the use of special barriers to prevent leakage.

- $\Delta P_x$: increase in tensile stress in prestressing steel

604. Analysis and Design

1. General

(1) Generally, the analysis of structure may be performed under the assumptions of linearly elastic materials and linearly elastic structural behavior, following the requirements of this subsection and the additional requirements (ACI 318).

(2) The material properties to be used in analysis are to conform to 604.2. However, the inelastic behavior of concrete based on the true variation of the modulus of elasticity with stress and the geometric nonlinearities, including the effects of initial deviation of the structure from the design geometry, are to be taken into account whenever their effects reduce the strength of the structure.

(3) The beneficial effects of the concrete's nonlinear behavior may be accounted for in the analysis and design of the structure to resist dynamic loadings.

(4) When required, the dynamic behavior of concrete structures may be investigated using a linear structural model, but soil-structural impedances are to be taken into account.

(5) The analysis of the structure under earthquake conditions may be performed under the assumption of elasto-plastic behavior due to yielding, provided that the requirements of Par 7 are satisfied.

2. Material Properties for Structural Analysis

(1) Specified Compressive Strength

The specified compressive strength of concrete, $f'_c$, is to be based on 28-day tests performed in accordance with specifications of this Society. (e.g., ASTM C172, ASTM C31 and ASTM C39)

(2) Early Loadings

For structures which are subjected to loadings before the end of the 28-day hardening period of concrete, the compressive strength of concrete is to be taken at the actual age of concrete at the time of loading.

(3) Early-Strength Concrete

For early-strength concrete, the age for the test for may be determined on the basis of the cement manufacturer's certificate.

(4) Modulus of Elasticity-Concrete

For the purpose of structural analyses and deflection checks, the modulus of elasticity of normal
weight concrete may be assumed as equal to $4733\sqrt{f_{c'}}$ N/mm$^2$ or determined from stress-strain curves developed by tests (see Fig 3.6.1) the latter method is used, the modulus of elasticity is to be determined using the secant modulus for the stress equal to 0.5 $f_{c'}$.

(5) Uniaxial Compression-Concrete

In lieu of tests, the stress-strain relation shown in Fig 3.6.1 may be used for uniaxial compression of concrete.

(6) Poisson Ratio

The Poisson ratio of concrete may be taken as equal to 0.17.

(7) Modulus of Elasticity-Reinforcement

The modulus of elasticity, $E_s$ of non-prestressed steel reinforcement is to be taken as $200\times10^3$ N/mm$^2$. The modulus of elasticity of prestressing tendons is to be determined.

(8) Uniaxial Tension-Reinforcement

The stress-strain relation of non-prestressed steel reinforcement in uniaxial tension is to be assumed as shown in Fig 3.6.2. The stress-strain relation of prestressing tendons is to be determined by tests, or taken from the manufacturers certificate.
(9) Yield Strength-Reinforcement
If the specified yield strength, $f_{y}$, of non-prestressed reinforcement exceeds 420 N/mm$^2$, the value $f_{y}$ used in the analysis is to be taken as the stress corresponding to a strain of 0.35 %.

3. Analysis of Plates, Shells, and Folded Plates
(1) In all analyses of shell structures, the theory employed in analysis is not to be based solely on membrane or direct stress approaches.
(2) The buckling strength of plate and shell structures is to be checked by an analysis which takes into account the geometrical imperfections of the structure, the inelastic behavior or concrete and the creep deformations of concrete under sustained loading.
(3) Special attention is to be devoted to structures subjected to external pressure and the possibility of their collapse (implosion) by failure of concrete in compression.

4. Deflection Analysis
(1) Immediate deflections may be determined by the methods of linear structural analysis.
(2) For the purposes of deflection analysis, the member stiffnesses are to be computed using the material properties specified in the design and are to take into account the effect of cracks in tension zones of concrete.
(3) The effect of creep strain in concrete is to be taken into account in the computations of deflections under sustained loadings.

5. Analysis and Design for Shear and Torsion
The applicable requirements of this Society or their equivalent are to be complied with in the analysis and design of members subject to shear or torsion or to combined shear and torsion.

6. Analysis and Design for Bending and Axial Loads
(1) Assumed Conditions
The analysis and design of members subjected to bending and axial loads are to be based on the following assumptions
(A) The strains in steel and concrete are proportional to the distance from the neutral axis.
(B) Tensile strength of the concrete is to be neglected, except in prestressed concrete members under unfactored loads, when the requirements in 603.5 are applied to.
(C) The stress in steel is to be taken as equal to $f_{y}$ times the steel strain, but not larger than $f_{y}$.
(D) The stresses in the compression zone of concrete are to be assumed to vary with strain according to the curve given in Fig. 3.6.1 or any other conservative rule. Rectangular distribution of compressive stress in concrete specified by the requirements (ACI 318) accepted by this Society may be used.
(E) The maximum strain in concrete at the ultimate state is not to be larger than 0.3 %

(2) Failure
The members in bending are to be designed in such a way that any section yielding of steel occurs prior to compressive failure of concrete.

7. Seismic Analysis
(1) Dynamic Approach
For structures to be located at sites known to be seismically active, dynamic analysis is to be performed to determine the response of the structure to design earthquake loading. The structure is to be designed to withstand this loading without damage. In addition, a ductility to experience deflections more severe than those resulting from the design earthquake loading without the collapse of the platform structure, its foundation or any major structural component.

(2) Design Conditions
The dynamic analysis for earthquake loadings is to be performed taking into account.
(A) The interaction of all components of the structure
(B) The compliance of the soil and the dynamic soil-structure interaction
(C) The dynamic effects of the ambient and contained fluids.

(3) Method of Analysis
The dynamic analysis for earthquake loadings may be performed by any recognized method, such as determination of time histories of the response by direct integration of the equations of motion, or the response spectra method.

(4) Ductility Check
In the ductility check, distortions at least twice as severe as those resulting from the design
earthquake are to be assumed. If the ductility check is performed with the assumption of elasto-plastic behavior of the structure, the selected method of analysis is to be capable of taking into account the nonlinearities of the structural model. The possibility of dynamic instability (dynamic buckling) of individual members and of the whole structure should be considered.

8. Seismic Design

(1) Compressive Strain
The compressive strain in concrete at critical sections (including plastic hinge locations) is to be limited to 0.3 %, except when greater strain may be accommodated by confining steel.

(2) Flexural Bending or Load Reversals
For structural members or sections subjected to flexural bending or to load reversals, where the percentage of tensile reinforcement exceeds 70 % of the reinforcement at which yield stress in the steel in reached simultaneously with compression failure in the concrete, special confining reinforcement and/or compressive reinforcement are to be provided to prevent brittle failure in the compressive zone of concrete.

(3) Web Reinforcement
(A) Web reinforcement (stirrups) of flexural members is to be designed for shear forces.
(B) The diameter of rods used as stirrups is not to be less than 10 mm.
(C) Only closed stirrups (stirrup ties) are to be used.
(D) The spacing of stirrups is not to exceed the lesser of \(d/2\) or 16 bar diameters of compressive reinforcement, where \(d\) is the distance from the extreme compression fiber to the centroid of tensile reinforcement. Tails of stirrups are to be anchored within a confined zone, i.e., turned inward.

(4) Splices
(A) No splices are allowed within a distance \(d\) from a plastic hinge.
(B) Lap splices are to be at least 30 bar diameters long but not less than 460 mm.

605. Design Details

1. Concrete Cover

(1) General
The following minimum concrete cover for reinforcing bars is required.
(A) Atmospheric zone not subjected to salt spray : 50 mm
(B) Splash and atmospheric zones subjected to salt spray and exposed to soil : 65 mm
(C) Submerged zone : 50 mm
(D) Areas not exposed to weather or soil : 40 mm
(E) Cover of stirrups may be 13 mm less than covers listed above.

(2) Tendons and Duct
The concrete cover of prestressing tendons and post-tensioning ducts is to be increased 25 mm above the values listed in (1).

(3) Sections Less than 500 mm Thick
In sections less than 500 mm thick, the concrete cover of reinforcing bars and stirrups may be reduced below the values listed in (1) ; however, the cover is not to be less than the following.
(A) 1.5 times the nominal aggregate size
(B) 1.5 times the maximum diameter of reinforcement, or 19 mm
(C) Tendons and post-tensioning duct covers are to have 12.5 mm added to the above.

2. Minimum Reinforcement

(1) For loadings during all phases of construction, transportation, and operation (including design environmental loading) where tensile stresses occur on a face of the structure, the following minimum reinforcement on the face is required.

\[
A_s = (f_t/f_c)bd_c
\]

\(A_s\) : Total cross section area of reinforcement
\(f_t\) : mean tensile strength of concrete
\[ f_y \]: yield stress of the reinforcing steel  
\[ b \]: width of structural element  
\[ d_e \]: effective tension zone, to be taken as \( 1.5C + 10d_b \)  
\[ C \]: cover of reinforcement  
\[ d_b \]: diameter of reinforcement bar

\( d_e \) should be at least 0.2 times the depth of the section but not greater than \( 0.5(h - x) \), where \( x \) is the depth of the compression zone prior to cracking and \( h \) is the section thickness.

(2) At intersections between structural elements, where transfer of shear forces is essential to the integrity of the structure, adequate transverse reinforcement is to be provided.

### 3. Reinforcement Details

(1) Generally, lapped joints should be avoided in structural members subjected to significant fatigue loading. If lapped splices are used in members subject to fatigue, the development length of reinforcing bars is to be twice that required by the requirements (ACI 318) recognized by this Society, and lapped bars are to be tied with tie wire.

(2) Reinforcing steel is to comply with the chemical composition specification of the requirements (ACI 318) recognized by this Society if welded splices are used.

### 4. Post Tensioning Ducts

(1) Ducting for post-tensioning ducts may be rigid and watertight. About 5% additional ducts are to be installed in main vertical tendon.

(2) A minimum wall thickness of duct is not to be less than 2 mm. Ducting is to comply with the required curvature.

(3) Where the using of rigid steel duct is unreasonable, semi-rigid steel duct may be used.

(4) All splices in steel tubes and semi-rigid duct shall be sleeved and the joints sealed with heat-shrink tape. Joints in plastic duct shall be fused or sleeved and sealed.

(5) The inside diameter of ducts shall be at least 6 mm larger than the diameter of the post-tensioning tendon in order to facilitate grout injection.

### 5. Post-Tensioning Anchorages and Couplers

(1) Anchorages for unbonded tendons and couplers are to develop the specified ultimate capacity of the tendons without exceeding anticipated set.

(2) Anchorages for bonded tendons are to endure at least 90% of the specified ultimate capacity of the tendons, when tested in an unbonded condition without exceeding anticipated set. However, 100% of the specified ultimate capacity of the tendons is to endure after the tendons are bonded in the member.

(3) Anchorage and the fittings are to be permanently protected against corrosion.

(4) Anchor fittings for unbonded tendons are to be capable of transferring to the concrete a load equal to the capacity of the tendon under both static and cyclical loading conditions.

### 6. Construction

#### 1. General

Construction methods and workmanship are to follow accepted practices as described in this section, and the specifications referred to by the requirements recognized by this Society.

#### 2. Mixing, Placing, and Curing of Concrete

(1) Mixing
Mixing of concrete is to conform with the requirements (e.g., ACI 318, ASTM C94 etc.) recognized by this Society.

(2) Cold Weather
In cold weather, concreting in air temperatures below 2°C should be carried out only if special precautions are taken to protect the fresh concrete from damage by frost. The temperature of the concrete at the time of placing is to be at least 4°C and the concrete is to be maintained at this or a higher temperature until it has reached a strength of at least 5 N/mm². Protection and insulation are to be provided to the concrete where necessary. The aggregates and water used in the mixing is are to be free from snow, ice and frost. The temperature of
the fresh concrete may be raised by heating the mixing water or the aggregates or both. Cement should never be heated nor should it be allowed to come into contact with water at a temperature greater than 60°C.

(3) Hot Weather
During hot weather, proper attention is to be given to ingredients, production methods, handling, placing, protection and curing to prevent excessive concrete temperatures or water evaporation which will impair the required strength or serviceability of the member or structure. The temperature of concrete as placed is not to exceed 30°C and the maximum temperature due to heat of hydration is not to exceed 65°C.

(4) Curing
Special attention is to be paid to the curing of concrete in order to ensure maximum durability and to minimize cracking. Concrete should be cured with fresh water, whenever possible, to ensure that the concrete surface is kept wet during hardening. Care should be taken to avoid the rapid lowering of concrete temperatures(thermal shock) caused by applying cold water to hot concrete surface.

(5) Sea Water
Sea water is not to be used for curing reinforced or prestressed concrete, although, if demanded by the construction program, "young" concrete may be submerged in sea water provided it has gained sufficient strength to withstand physical damage. When there is doubt about the ability to keep concrete surfaces permanently wet for the whole of the curing period, a heavy duty membrane curing compound should be used.

(6) Temperature Rise
The rise of temperature in the concrete, caused by the heat of hydration of the cement, is to be controlled to prevent steep temperature stress gradients which could cause cracking of the concrete. Since the heat of hydration may cause significant expansion, members must be free to contract, so as not to induce excessive cracking. In general, when sections thicker than 610 mm are concreted, the temperature gradients between internal concrete and external ambient conditions are to be kept below 20°C.

(7) Joints
Construction joints are to be made and located in such a way as not to impair the strength and crack resistance of the structure. Where a joint is to be made, the surface of the concrete is to be thoroughly cleaned and all laitance and standing water removed. Vertical joints are to be thoroughly wetted and coated with neat cement grout or equivalent enriched cement paste or epoxy coating immediately before placing of new concrete.

(8) Watertight Joints
Whenever watertight construction joints are required, in addition to the above provisions, the heavy aggregate of the existing concrete is to be exposed and an epoxide-resin bonding compound is to be sprayed on just before concreting. In this case, the neat cement grout can be omitted.

3. Reinforcements
(1) The reinforcement is to be free from loose rust, grease, oil, deposits of salt or any other material likely to affect the durability or bond of the reinforcement.
(2) The specified cover to the reinforcement is to be maintained accurately. Special care is to be taken to correctly position and rigidly hold the reinforcement so as to prevent displacement during concreting.

4. Prestressing Tendons, Ducts and Grouting
(1) General
Further guidance on prestressing steels, sheathing, grouts and procedures to be used when storing, making up, positioning, tensioning and grouting tendons will be found in the relevant requirements(ACI 318, PCI, FIP etc.) recognized by this Society.
(2) Cleanliness
All steel for prestressing tendons is to be clean and free from grease, insoluble oil, deposits of salt or any other material likely to affect the durability or bond of the tendons.
(3) Storage
(A) During storage, prestressing tendons are to be kept clear of the ground and protected from weather, moisture from the ground, sea spray and mist.
(B) No welding, flame cutting or similar operations are to be carried out on or adjacent to prestressing tendons under any circumstances where the temperature of the tendons could be
(4) Protective Coatings
Where protective wrappings or coatings are used on prestressing tendons, they are to be chemically neutral so as not to produce a chemical or electrochemical corrosive attack on the tendons.

(5) Entry of Water
(A) All ducts are to be watertight and all splices carefully taped to prevent the ingress of water, grout or concrete.
(B) During construction, the ends of ducts are to be capped and sealed to prevent the entry of sea water.
(C) Ducts may be protected from excessive rust by the use of chemically neutral protective agents such as vapor phase inhibitor powder.

(6) Grouting
(A) Where ducts are to be grouted, all oil or similar material used for internal protection of the sheathing is to be removed before grouting. However, water-soluble oil used internally in the ducts or on the tendons may be left on, to be removed by the initial portion of the grout.
(B) Ducts are to be cleaned with fresh water before grouting.

(7) Air Vents
Air vents are to be provided at all crests in the duct profile.

(8) Procedures
(A) For long vertical tendons, the grout mixes, admixtures and grouting procedures are to be checked to ensure that no water is trapped at the upper end of the tendon due to excessive bleeding or other causes.
(B) Suitable admixtures known to have no injurious effects on the metal or concrete may be used for grouting to increase workability and to reduce bleeding and shrinkage.
(C) Temperature of members must be maintained above 10°C for at least 48 hours after grouting.
(D) Holes left by unused ducts or by climbing rods of slipforms are to be grouted in the same manner as described above.

Section 7 Foundation

701. General

1. Application
(1) Scope
Soil investigations, design considerations for the supporting soil, and the influence of the soil on the foundation structure, are covered in this Chapter.
(2) Guideline
The degree of design conservatism should reflect prior experience under similar conditions, the manner and extent of data collection, the scatter of design data, and the consequences of failure. For cases where the limits of applicability of any method of calculation employed are not well defined, or where the soil characteristics are quite variable, more than one method of calculation or a parametric study of the sensitivity of the relevant design data is to be used.

702. Site Investigation

1. General
(1) The actual extent, depth and degree of precision applied to the site investigation program are to reflect the type, size and intended use of the structure, familiarity with the area based on previous site studies or platform installations, and the consequences which may arise from a failure of the foundation.
(2) For major structures, the site investigation program is to consist of the following three phases.
   (A) Sea Floor Survey to obtain relevant geophysical data (see Par 2)
   (B) Geological Survey to obtain data of a regional nature concerning the site. (see Par 3)
   (C) Subsurface Investigation and Testing to obtain the necessary geotechnical data.
(3) The results of these investigations are to be the bases for the additional site related studies which are listed in Par 5.
(4) A complete site investigation program is to be accomplished for each offshore structure. However, use of the complete or partial results of a previously completed site investigation as the design basis for another similarly designed and adjacent offshore structure is permitted when the adequacy of the previous site's investigation for the new location is satisfactorily demonstrated.

(5) When deciding the area to be investigated, due allowance is to be given to the accuracy of positioning devices used on the vessel employed in the site investigation to ensure that the data obtained is pertinent to the actual location of the structure.

2. Sea Floor Survey

Geophysical data for the conditions existing at and near the surface of the sea floor are to be obtained. The following information is to be obtained where applicable to the planned structure.

(A) Soundings or contours of the sea bed
(B) Position of bottom shapes which might affect scour
(C) The presence of boulders, obstructions, and small craters
(D) Gas seeps
(E) Shallow faults
(F) Slump blocks
(G) Ice scour or sea floor sediments
(H) Subsea permafrost or ice bonded soils

3. Geological Survey

(1) Data of the regional geological characteristics which can affect the design and siting of the structure. Such data are to be considered in planning the subsurface investigation, and they are also to be used to assure that the findings of the subsurface investigation are consistent with known geological conditions.

(2) Where necessary, an assessment of the seismic activity at the site is to be made. Particular emphasis is to be placed on the identification of fault zones, the extent and geometry of faulting and attenuation effects due to conditions in the region of the site.

(3) For structures located in a producing area, the possibility of sea floor subsidence due to a drop in reservoir pressure is to be considered.

4. Subsurface Investigation and Testing

(1) The subsurface investigation and testing program is to obtain reliable geotechnical data concerning the stratigraphy and engineering properties of the soil. These data are to be used to assess whether the desired level of structural safety and performance can be obtained and to assess the feasibility of the proposed method of installation.

(2) Consistent with the stated objective, the soil testing program is to consist of an adequate number of in-situ tests, borings and samplings to examine all important soil and rock strata. The testing program is to reveal the necessary strength, classification and deformation properties of the soil. Further tests are to be performed as needed, to describe the dynamic characteristics of the soil and the static and cyclic soil-structure interaction.

(3) For pile-supported structures, the minimum depth of at least one bore hole, for either individual or clustered piles, is to be the anticipated length of piles plus a zone of influence. The zone of influence is to be at least 15.2 m or 1.5 times the diameter of the cluster, whichever is greater, unless it can be shown by analytical methods that a lesser depth is justified. Additional bore holes of lesser depth are required if discontinuities in the soil are likely to exist within the area of the structure.

(4) For a gravity-type foundation, the required depth of at least one boring is to be at least equal to the largest horizontal dimension of the base. In-situ tests are to be carried out, where possible, to a depth that will include the anticipated shearing failure zone.

(5) A reasonably continuous profile is to be obtained during recovery of the boring samples. The desired extent of sample recovery and field testing is to be as follows.

(A) The recovery of the materials to a depth of 12 m below the mudline is to be as complete as possible. Thereafter, samples at significant changes in strata are to be obtained, at approximately 3 m intervals to 61 m and approximately 8 m intervals below 61 m.

(B) At least one undrained strength test (vane, drop cone, unconfined compression, etc) on selected recovered cohesive samples is to be performed in the field.

(C) Where practicable, a standard penetration test or equivalent on each significant sand stratum is to be performed, recovering samples where possible.
(D) Field samples for laboratory work are to be retained and carefully packaged to minimize changes in moisture content and disturbance.

(6) Samples from the field are to be sent to a recognized laboratory for further testing. They are to be accurately labeled and the results of visual inspection recorded. The testing in the laboratory is to include at least the following:
   (A) Perform unconfined compression tests on clay strata where needed to supplement field data.
   (B) Determine water content and Atterberg limits on selected cohesive samples
   (C) Determine density of selected samples
   (D) As necessary, develop appropriate constitutive parameters or stress-strain relationship from either unconfined compression tests, unconsolidated undrained triaxial compression tests, or consolidated undrained triaxial compression tests
   (E) Perform grain size analysis, complete with percentage passing 200 sieve, on each significant sand or silt stratum

(7) For pile-supported structures, consideration is to be given to the need for additional tests to adequately describe the dynamic characteristics of the soil and the static and cyclic lateral soil-pile.
   (A) Shear strength tests with pore pressure measurements. The shear strength parameters and pore-water pressures are to be measured for the relevant stress conditions
   (B) Cyclical loading tests with deformation and pore pressure measurements to determine the soil behavior during alternating stress
   (C) Permeability and consolidation tests performed as required

5. Documents

The foundation design documentation mentioned in Sec 1 is to be submitted for review. As applicable, the results of studies to assess the following effects are also to be submitted.
   (A) Scouring potential of the sea floor
   (B) Hydraulic instability and the occurrence of sand waves
   (C) Instability of slopes in the area where the structure is to be placed
   (D) Liquefaction and other soil instabilities
   (E) For Arctic area, possible degradation of subsea permafrost layers as a result of the production of hot oil

703. Foundation Design Requirements

1. General

The loadings use in the analysis of the safety of the foundation are to include those defined in Par 7 and those experienced by the foundation during installation. Foundation displacements are to be evaluated to the extent necessary to ensure that they are within limits which do not impair the intended function and safety of the structure. The soil and the structure are to be considered as an interactive system, and the results of analysis, as required in subsequent paragraphs, are to be evaluated from this point of view.

2. Cyclic Loading Effects

(1) This influence of cyclic loading on soil properties is to be considered. For gravity structures in particular, possible reduction of soil strength is to be investigated and employed in design. In particular the following conditions are to be considered:
   (A) Design storm during the initial consolidation phase
   (B) Short-term effects of the design storm
   (C) Long-term cumulative effects of several storms, including the design storm

(2) Reduced soil strength characteristics resulting from these conditions are to be employed in design. In seismically active zones, similar deteriorating effects due to repeated loadings are to be considered. Other possible cyclic load effects, such as changes in load-deflection characteristics, liquefaction potential and slope stability are also to be considered, and these effects should be accounted for when they will affect the design.

3. Scour

Where scour is expected to occur, either effective protection is to be furnished soon after the installation of the structure, or the depth and lateral extent of scouring, as evaluated in the site investigation program, is to be accounted for in design.
4. Deflection and Rotations

Tolerable limits of deflections and rotations are to be established based on the type and function of the platform, and the effects of those movements on risers, piles and other structures which interact with the platform. Maximum allowable values of platform movements, as limited by these structural considerations or overall platform stability, are to be considered in the design.

5. Soil Strength

(1) The ultimate strength or stability of soil is to be determined using test results which are compatible with the method selected.

(2) In a total stress approach the total shear strength of the soil obtained from simple tests is used. A total stress approach largely ignores changes in the soil's pore water pressure under varying loads and the drainage conditions at the site.

(3) When an effective stress approach is used effective soil strength parameters and pore water pressures are determined from tests which attempt to predict in-situ total stresses and pore pressures.

6. Dynamic and Impact Considerations

(1) For dynamic and impact loading conditions, a realistic and compatible treatment is to be given to the interactive effects between the soil and structure. When analysis is required it may be accomplished by lumped parameter, foundation impedance functions, or by continuum approaches including the use of finite element methods. Such models are to include consideration of the internal and radiational damping provided by the soil and the effects of soil layering.

(2) Studies of the dynamic response of the structure are to include, where applicable, consideration of the nonlinear and inelastic characteristics of the soil, the possibilities of deteriorating strength and increased or decreased damping due to cyclic soil loading, and the added mass of soil subject to acceleration. Where applicable, the influence of nearby structures is to be included in the analysis.

7. Loading Conditions

(1) Those loadings which produce the worst effects on the foundation during and after installation are to be taken into account. Post installation loadings to be checked are to include at least those relating to both the operating and design environmental conditions, combined in the following manner.

(A) Operating environmental loading combined with dead and maximum live loads appropriate to the function and operations of the structure.

(B) Design environmental loading combined with dead and live loads appropriate to the function and operations of the structure during the design environmental conditions

(C) Design environmental loading combined with dead load and minimum live loads appropriate to the function and operations of the structure during the design environmental conditions

(2) For areas with potential seismic activity, the foundation is to be designed for sufficient strength to sustain seismic loads.

8. Anchoring System

(1) Where the anchoring utilizes piles, the requirements in these Rules applicable to piles are to be used. The loads at the mooring line attachments are to be calculated and the pile's local strength is to be checked.

(2) Where the anchoring utilizes gravity anchors, the requirements in these Rules applicable to gravity based structures are to be used.

(3) Where platform are permanently and partially supported by a mooring system, the analysis of the platform's foundation is to include the interactive effects of the mooring system.

(4) Other types of anchoring will be specially considered.

9. Loads and Soil conditions Due to Temporally Situated Structures

(1) Changes in soil conditions due to temporarily situated platform such as self-elevating drilling units, workover rigs or tender rigs placed near the structures are to be assessed and investigated.

(2) These changes and their influence on the structure are to be incorporated in the foundation design to ensure that structure's function and safety are not impaired.
704. Pile Foundation

1. General
   (1) The effects of axial, bending and lateral loads are to be accounted for in the design of indi-
       vidual and group piles.
   (2) The design of a pile is to reflect the interactive behavior between the soil and the pile and be-
       tween the pile and the structure. Methods of pile installation are to be consistent with the type 
       of soil at the site, and with the installation equipment available. Pile driving is to be carried 
       out and supervised by qualified and experienced personnel, and driving records are to be ob-
       tained and submitted for review.
   (3) Should unexpectedly high or low driving resistance or other conditions be encountered which 
       lead to a failure of the pile to reach its desired penetration, a reevaluation of the pile's capacity 
       is to be carried out considering the parameters resulting from the actual installation.
   (4) Where necessary, the effects of bottom instability in the vicinity of the structure are to be 
       assessed.

2. Axial Piles
   For piles in compression, the axial capacity is to be considered as consisting of the skin friction, 
   $Q_s$ developed along the length of the pile, and the end bearing, $Q_e$ at the tip of the pile. The ax-
   ial capacity of a pile subjected to tension is to be equal to or less than the skin friction alone. 
   Predictions of the various parameters needed to evaluate $Q_s$ and $Q_e$ are to be accomplished using a 
   recognized analytical method or another method shown to be more appropriate to the conditions at 
   the site. When required, the acceptability of any method used to predict the components of pile re-
   sistance is to be demonstrated by showing satisfactory performance of the method under conditions 
   similar to those existing at the actual site. The results of dynamic pile driving analysis alone are 
   not to be used to predict the axial load capacity of a pile.

3. Factors of Safety for Axial Piles
   (1) When the pile is subjected to the three loading cases described in 703. 7 and the ultimate ca-
       pacities are evaluated using the above cited API method, the allowable values of axial pile 
       bearing and pullout loads are to able values of axial pile bearing and pullout loads are to be 
       determined by dividing the ultimate capacities obtained above. When ultimate capacities are cal-
       culated using the method described in Par 2, the minimum safety factor obtained about 703. 7 
       (1) (A) is 2.0, and 1.5 about (1) (B) or (1) (C).
   (2) For the design earthquake, the factor of safety is to be specially considered.

4. Laterally Loaded Piles
   (1) In the evaluation of the pile's behavior under lateral loadings, the combined load-deflection char-
       acteristics of the soil and pile, and the pile and the structure are to be taken into account. The 
       representation of the soil's lateral deflection when it is subjected to lateral loads is to adequately 
       reflect the deterioration of the lateral bearing capacity when the soil is subjected to cyclic 
       loading. The description of the lateral load versus deflection characteristics for the various soil 
       strata is to be based on constitutive data obtained from suitable soil tests.
   (2) Reference is to be made for a procedure to evaluate the load-deflection characteristics of later-
       ally loaded piles. However, the use of alternative methods is permitted when they are more ap-
       propriate for conditions at the site.
   (3) Where applicable, the rapidly deteriorating cyclic bearing capacity of stiff clays, especially those 
       exhibiting the presence of a secondary structure, is to be accounted for in the design.

5. Anchor Piles
   (1) When lateral loads are directly applied to a pile such as in the case when it is used to anchor 
       a mooring line suitable load factors greater than 1.0 are to be used to increase the magnitudes of 
       the lateral load effects resulting from the load conditions of 703. 7.
   (2) Calculation of the soil capacity and the pile stresses is to be based on consideration of the 
       modified loads.

6. Pile groups
   (1) Where applicable, the effects of close spacing on the load and deflection characteristics of pile 
       groups are to be determined.
   (2) The allowable load for a group, both axial and lateral, is not to exceed the sum of the appa-
rent individual pile allowable loads reduced by a suitable factor.

7. Connections Between Piles and Structure

(1) The loads acting on the platform may be transferred to the piles by connecting the jacket legs or pile sleeves to the piles by welding, grouting the annulus between the jacket leg or pile sleeve and the pile, or by use of mechanical devices such as pile grippers. The design of the grouted pile to structure connection should consider the use of mechanical shear connectors as their presence increase the strength of the connection, and eliminates any effect of long term grouting shrinkage.

(2) Adequate clearance between the pile and the jacket leg should be provided for proper placement of the grout.

(3) Reliable means for the introduction of the grout to the annulus should be provided to ensure complete filling of the annulus and to minimize the possibility of dilution of the grout and the formation of voids in the grout.

(4) If mechanical devices are used their strength and fatigue characteristics are to be adequately demonstrated by analysis, testing or experience.

705. Gravity Structures

1. General

(1) The stability of the foundation with regard to bearing and sliding failure modes is to be investigated employing the soil shear strengths determined in accordance with 702.4 and 703.2.

(2) The effects of adjacent structures and the variation of soil properties in the horizontal direction are to be considered where relevant.

(3) Where leveling of the site is not carried out, the predicted tilt of the overall structure is to be based on the average bottom slope of the sea floor and the tolerance of the elevation measuring device used in the site investigation program.

(4) Differential settlement is also to be calculated and the tilting of the structure caused by this settlement is to be combined with the predicted structural tilt. Any increased loading effects caused by the tilting of the structure are to be considered in the foundation stability requirements of Par 2.

When underpressure or overpressure is experienced by the sea floor under the structure, provision is to be made to prevent piping which could impair the integrity of the foundation. The influence of hydraulic and slope instability, if any, is to be determined for the structural loading cases of 703.7 (1).

(5) Initial consolidation and secondary settlements, as well as permanent horizontal displacements, are to be calculated.

2. Stability

(1) The bearing capacity and lateral resistance are to be calculated under the most unfavorable combination of loads.

(2) Possible long term redistribution of bearing pressures under the base slab are to be considered in order to ensure that the maximum edge pressures are used in the design of the perimeter of the base.

(3) The lateral resistance of the platform is to be investigated with respect to various potential shearing planes. Special consideration is to be given to any layers of soft soil.

(4) Calculations for overturning moment and vertical forces induced by the passage of a wave are to include the vertical pressure distribution across the top of the foundation and along the sea floor.

(5) The capacity of the foundation to resist a deep-seated bearing failure is to be analyzed. In lieu of a more rigorous analysis, where uniform soil conditions are present or where conservatively chosen soil properties are used to approximate a non-uniform soil condition, and where a trapezoidal distribution of soil pressure is a reasonable expectation, the capacity of the foundation to resist a deep-seated bearing failure can be calculated by standard bearing capacity formulas applicable to eccentrically loaded shallow foundations. Alternatively, slip-surface methods, covering a range of kinematically possible deep rupture surfaces can be employed in the bearing capacity calculations.

(6) The maximum allowable shear strength of the soil is to be determined by dividing the ultimate shear strength of the soil by the minimum safety factors given below.
When the ultimate soil strength is determined by an effective stress method, the safety factor is to be applied to both the cohesive and frictional terms. If a total stress method is used, the safety factor is to be applied to the undrained shear strength.

(7) The minimum safety factors to be obtained, when employing a standard bearing capacity formulation and various trial sliding failure planes with the loading conditions of 703. 7, are 2.0 for (1) (A), and 1.5 for (B) and (C). The safety factors to be obtained when considering the Design Earthquake will be specially considered.

(8) Where present, the additional effects of penetrating walls or skirts which transfer vertical and lateral loads to the soil are to be investigated as to their contribution to bearing capacity and lateral resistance.

3. Soil Reaction on the Structure

(1) For conditions during and after installation, the reaction of the soil against all structural members seated on or penetrating into the sea floor is to be determined and accounted for in the design of these members.

(2) The distribution of soil reactions is to be based on the results obtained in 702. 4.

(3) Calculations of soil reactions are to account for any deviation from a plane surface, the load-deformation characteristics of the soil and the geometry of the base of the structure. Where applicable, effects of local soil stiffening, non-homogeneous soil properties, as well as the presence of boulders and other obstructions, are to be accounted for in design.

(4) During installation, consideration is to be given to the possibility of local contact pressures due to irregular contact between the base and the sea floor. These pressures are additive to the hydrostatic pressure.

(5) An analysis of the penetration resistance of structural elements projecting into the sea floor below the foundation structure is to be performed.

(6) The design of the ballasting system is to reflect uncertainties associated with achieving the required penetration of the structure.

(7) Since the achievement of the required penetration of the platform and its skirts is of critical importance, the highest expected values of soil strength are to be used in the calculation of penetration.

Section 8 Installation

801. Guidance

1. Definition

(1) For the stages of transportation, movement of jacket from cargo barge, installation and welding on platform installation, API RP 2A Sec 5 may be applied for reference at those stages. For the review, those procedures are to be submitted to this Society.

(2) During the installation work, supervision is to be carried out for confirmation of progressing whether it is carried out in accordance with the procedure. And the surveyor is to be attended for this supervision.

802. Submission of Calculation

1. Structures

Structural calculation for stress of installation described in API RP 2A 2.4 is to be submitted for the confirmation that the stress in platform construction is not affect to the foundation and effectiveness.

To verify that stresses of platform structural members do not affect the strength of the foundation of structure and overall platform structure, the structural calculation report contained the installation force in accordance with the API RP 2A 2.4 is to be submitted.

2. Stability

When the platform structural members unloaded from the barge, compartment flooding is controlled at floating condition or settled down at installation site with similar methods, necessary stability is to be calculated. And to verify the appropriate stability for considerate work, hydrostatic stability analytic reports of the platform are to be submitted.
Section 9  Marine Operation

901. General

1. General
The effects which may be induced in the structure during the marine operations required for the transportation and installation of the structure and equipment are to be considered. The emphasis of this Chapter is the influence which these operations may have on the safety and integrity of the structure.

2. Application
   (1) In this Rules, the followings may be included in marine operations in general;
       (A) Lifting and mooring operation
       (B) Load-out
       (C) Construction afloat
       (D) Towing
       (E) Launching and uprighting
       (F) Submergence
       (G) Pile installation
       (H) Final field erection
       (I) Removal operation
   (2) For all marine operations except towing, the skilled supervision is being provided and the operations are being executed with satisfaction of the Surveyor. During a tow, the towage master is to assure that proper procedures are followed. The Operator may also optionally request that a Surveyor be present during a tow.

902. Documentation

1. General
The extent of documentation and analysis(see 903.) of marine operations is to be commensurate with the size and type of structure involved, the particular operation being considered, the extent of past experience with similar operations, and the severity of the expected environmental conditions.

2. Report
   (1) A report on the marine operations planned to transport and install the structure is to be developed and submitted for use in association with the review of the analyses required in 903.
   (2) For structures requiring a significant amount of construction while afloat(e.g., large concrete gravity structures), documentation of the operations involved is to be included in this report.
   (3) The purpose of this report is to demonstrate that the strength and integrity of the structure are not reduced or otherwise jeopardized by the marine operations. Generally, this report is to contain the following information.
      (A) Description of the marine operations to be performed and the procedures to be employed.
      (B) For operations which do not govern design of the structure, a description of the engineering logic, experience or preliminary calculations supporting this conclusion.
      (C) For operations which govern design of the structure, the assumptions, calculations and results of the analyses required in 903.
      (D) For structures to be uprighted or submerged by selective ballasting, a detailed description of the mechanical, electrical and control systems to be employed, the ballasting schedule and supporting calculations.

903. Analysis

1. Loads
   (1) Analyses are to be performed to determine the type and magnitude of the loads and load combinations to which the structure will be exposed during the performance of marine operations.
   (2) Particular attention is to be given to inertial, impact, and local loads which are likely to occur during marine operations.
(3) Where significant fatigue damage occurs during marine operations, it shall be included in calculating the total fatigue lives.

2. Stress

(1) Where temporary attachments or appurtenances (tie-downs, skid beams, etc.) are utilized, analyses are to be performed to ensure that these items and their supporting structure have sufficient strength to withstand the type and magnitude of loads with the appropriate factor of safety required in Para 1.

(2) The strength criteria of Sec 5 and 6 for steel structures and concrete structures, respectively, are to be employed in this determination.

3. Stability

(1) Analyses are to be performed to ensure that the structure, or its means of support where such exist, has sufficient hydrostatic stability and reserve buoyancy to allow for successful execution of marine operations.

(2) For large or unusual structures, an experimental determination of the center of gravity of the structure and its means of support, where such exist, is to be performed.

904. Fitness to Tow Certificate

1. General

(1) Upon request by the Operator and where authorized to do so, this Society will undertake the services required for the issuance of a fitness to tow certificate.

(2) The adequacy of the towlines, attachments and towing vessels will not be reviewed by this Society.

(3) Review by this Society solely for purposes of classification is not to be considered a replacement for the review commonly required for the issuance of a towage certificate.
CHAPTER 5  MACHINERY INSTALLATIONS

Section 1  General

101. General

1. The requirements in this Chapter apply to the machinery installations of the installation. Equipment and systems of the drilling and production systems are not covered by these requirements.

2. The machinery installations of units, except where specially required in this chapter, are to comply with the relevant requirements in Ch 5, Ch 7, Ch 8 and Ch 9 of Guidance for Mobile Offshore Drilling Units.

3. Piping system design, fabrication and testing are to comply with the requirements in this Chapter and standards recognized by the Society, such as ASME B31, "Code for Pressure Piping", latest edition.

102. Plans and documents to be Submitted

The following plans and documents are to be submitted in triplicate to the Society.

(1) General arrangement of machinery spaces
(2) Plans and documents of boilers and pressure vessels, engines and other equipments specified in Pt 5, Ch 1 of Rules for the Classification of Steel Ships.
(3) Plans and documents specified in Pt 5, Ch 1, 202. of Rules for the Classification of Steel Ships, where applicable.
(4) An arrangement plan clearly indicating the hazardous areas as outlined in 103.
(5) Complete particulars of the ventilating system including capacities of fans, number of complete air changes per minute, air flow, area subject to positive and negative pressure, and location of self-closing doors.
(6) A description of the ventilating system for all hazardous areas
(7) Piping and instrumentation diagram

103. Definition

1. Hazardous space means space to be classified on the basis of the latest edition of API RP 505, "Recommended Practice for Classification of Locations for Electrical Installations at Petroleum Facilities Classified as Class I, Zone 0, Zone 1 and Zone 2", or an equivalent recognized standard.

Section 2  Engines, Boilers and Pressure Vessels

201. General

1. Exhaust gasses of internal combustion engines and boilers are to be discharged outside of all hazardous areas and exhaust outlets of internal combustion engines are to be fitted with suitable spark arresting devices.

2. Air intakes for internal combustion engines and boilers are to be located not less than 3 m away from hazardous space.

202. Installations in hazardous areas

1. Internal combustion engines are not to be installed in Zone 0 hazardous areas, as defined by API RP 505.

2. When Internal combustion engines are installed in Zone 1 and Zone 2, such installation will be subject to special consideration. Fired boilers are not to be installed in hazardous areas.
203. Fire detection of machinery spaces
Spaces having boilers, fired heaters or engines are to be fitted with an automatic fire detection system that will secure the fuel to the space. Additionally, on manned platforms, the system is to sound an alarm.

204. Boilers and pressure vessels
1. Boilers and pressure vessels are to be designed, constructed and tested in accordance with the American Society of Mechanical Engineers' "Boiler and Pressure Vessel Code", latest edition.
2. For boilers and fired heaters, firing arrangements are to be arranged so that fuel is automatically cut off on loss of flame.
3. When boilers and fired heaters using gas as fuel are located in an enclosed space, the space is to be adequately ventilated and it is to be fitted with an effective gas detection system; a fuel valve is to automatically close upon detection of gas.
4. Arrangements for using crude oil as fuel will require special consideration.

205. Diesel and gas turbine engines
Engines will be accepted on the basis of the manufacturer's guarantee, subject to the carrying out of a satisfactory performance test witnessed by the Surveyor after installation. Engines and their installation are to be to the satisfaction of the Society.

206. Ventilation of machinery spaces
1. Attention is to be given to ventilation inlet and outlet locations and air flow in order to minimize the possibility of cross contamination. Ventilation inlets are to be located in non-hazardous areas.
2. Ventilation for hazardous areas is to be completely separated from that for non-hazardous areas.

Section 3 Auxiliaries and Piping Arrangement

301. Vent pipes
1. General
The structural arrangement of all tanks is to be such as to permit the free passage of air and gases from all parts of the tanks to the vent pipes. Vent pipes are to be arranged to provide adequate drainage under normal conditions.
2. Size
(1) The diameter of each vent pipe is not to be less than 38 mm inside diameter for fresh water tanks and 63 mm inside diameter for oil tanks unless specially approved otherwise.
(2) Where tanks are to be filled by pump pressure, the aggregate area of the vents in the tank is to be at least 125% of the effective area of the filling line. However, the vents need not exceed the above minimum sizes when overflows of which the area is to be at least 125% of the effective area of the filling line are fitted. Notwithstanding the above, the pump capacity and pressure head are to be considered in the sizing of vents and overflows.

302. Sounding pipes
1. General
Tanks are to be fitted with sounding pipes not less than 38 mm inside diameter and where a sounding pipe exceeds 20 m in length, the minimum internal diameter is to be at least 50 mm. They are to be led as straight as possible from the lowest part of the tank to a position which is always accessible.
2. Gauge glasses
   (1) Tanks may be fitted with suitable gauge glasses in lieu of sounding pipes, provided they are fitted with a valve at each end of the gauge and adequately protected from mechanical damage.
   (2) Gauge glasses on tanks containing combustible liquids are to be of flat shape and of heat resisting quality, and to have approved self-closing valves at each end.

303. Fuel oil systems

1. General
   Fuel oil pumping arrangements are to be distinct from the other pumping systems as far as practicable, and means are to be provided for preventing dangerous interconnection.

2. Pipes in fuel oil tanks
   (1) Oil pipes and other pipes, where passing through fuel oil tanks, are to be of steel, except that other materials may be considered where it is demonstrated that the material is suitable for the intended service.
   (2) All packing is to be of a composition not affected by oil.

3. Drip pans
   Pumps, strainers, etc., requiring occasional examination are to have drip pans.

4. Valves on fuel oil tanks
   (1) Where pipe lines emanate from oil tanks at such a level that they will be subjected to a static head of oil from the tank, they are to be fitted with positive closing valves located at the tank or where the pipe line enters the machinery space. Arrangements are to be provided for closing them from a readily accessible and safe location outside of the compartment in which the valve is located.
   (2) Where independent filling lines are fitted, they are to enter at or near the top of the tank; but if this be impracticable, they are to be fitted with non-return valves at the tank.

5. Remote shutdown of pumps
   Fuel oil transfer pumps, fuel oil unit pumps and other similar fuel pumps are to be fitted with remote controls situated outside the space concerned so that they may be stopped in the event of a fire arising in the space in which they are located.

6. Fuel oil tanks and drains
   (1) The fuel oil overflows, drains from fuel and lubricating oil tanks and from drip pans of oil pumps and tanks are to be led to a drain tank fitted with air and sounding pipes and an independent suction from the fuel oil transfer pumps.
   (2) Non-return valves are to be fitted in drain lines entering the drain tanks where backflow would present a hazard. Suitable means are to be provided for pumping out these drain tanks.
   (3) Tanks not forming part of the platform structure are to have suitable drip pans.
   (4) Service tanks are to be located at a sufficient height to permit gravity flow to the service pump section.

304. Fuel oil storage for helicopter facilities

1. Areas where fuel oil storage tanks for helicopters are located and fueling operations conducted are to be suitably isolated from areas which contain a source of vapor ignition.

2. Fuel oil storage tanks are to be provided with vents in accordance with 301. The vents are to extend to at least 2.4 m above the deck.

3. Fuel oil storage tanks are to be of approved metallic construction. Special attention is to be given to the design, mounting and securing arrangements and electrical bonding of the tank and fuel oil transfer system.

4. The storage and handling area is to be permanently marked.

5. Coamings or other similar arrangements are to be provided at each fuel oil storage tank and are to
be sufficient in height to retain the contents of the storage tank plus fire-extinguishing agents where provided.
CHAPTER 6 ELECTRICAL INSTALLATIONS, SAFETY FEATURES AND FIRE PROTECTION

Section 1 Electrical Installation

101. General

1. General

(1) The requirements in this Chapter apply to the electrical installations of the platform. Components of the drilling and production systems are not covered by these requirements.

(2) Electrical installations are to comply with the requirements of standards recognized by the Society.

2. Plans and documents to be submitted

The following plans and documents are to be submitted in triplicate to the Society.

(1) Generators and motors
   Complete rating, class of insulation and rated ambient temperature, rated temperature rise and standard to which manufactured.

(2) Switchgear and switchboards
   Arrangements and details, front view, installation arrangements and wiring diagram including a schematic diagram.

(3) Motor-control equipment
   Terminal arrangements, degree of enclosure and wiring diagram.

(4) Wiring
   Plans of all wiring, complete feeder list, giving for each feeder and branch circuit the load, wire size, type of wire or cable, rating or setting of circuit breakers, rating of fuses and switches, interrupting capacity of circuit breakers and fuses.

(5) Short-circuit data
   Data are to be submitted giving the maximum calculated short-circuit current at each point in the distribution system.

(6) Hazardous areas
   A plan showing the electrical equipment installed in hazardous areas (see Pt 7, Ch 1, Sec 11 of Rules for Classification of Steel Ships).

(7) Cathodic protection
   Details of impressed-current-cathodic protection system.

(8) Other plans and documents deemed necessary by the Society.

102. Electrical Installations

1. General consideration

(1) Watertight or weatherproof equipment
   Electrical equipment exposed to the weather or located where it would be exposed to other severe moisture conditions is to be weatherproof or watertight.

(2) Corrosion-resistant parts
   Enclosures, working and other parts of electrical equipment which would be damaged or rendered ineffective by corrosion are to be made of corrosion-resistant materials or of material rendered corrosion-resistant.

(3) Grounding arrangements
   (A) Where not obtained through normal construction, arrangements are to be provided to effectively ground all machinery, metal structures of derricks, masts and helicopter platforms.
   (B) Grounding arrangements are to be provided for tending vessels.

(4) Standards
   Standards recognized by the Society are to be complied with in the manufacture and testing of motors, generators, cables and wiring, and also in the provision of overload, over-current and short-circuit protection.

2. Installations in hazardous areas

(1) Installations in hazardous areas are to comply with Pt 7, Ch 1, Sec 11 of Rules for
Classification of Steel Ships.

(2) In general, equipment in hazardous areas is to be explosion-proof, intrinsically safe, or purged and pressurized.

(3) Explosion-proof and intrinsically safe equipment is to be of an approved type. Purged and pressurized equipment is to comply with a recognized standard.

3. Auxiliary power supply

An auxiliary power supply is to be provided. The auxiliary power supply is to have a capacity sufficient to power all electrical equipment required to maintain safety of operations in the event of failure in the primary electrical power supply.

4. Emergency source of power for manned platforms

(1) General

A self-contained emergency source of power is to be installed in a non-hazardous space. Its location and arrangement are to be such as to insure that a fire or other failure in a space containing the main source, the auxiliary source, or in any space containing internal combustion machinery, any oil-fired boiler or oil fuel unit will not interfere with the supply or distribution of emergency power.

(2) Power supply

The power available is to be sufficient to supply for at least 18 hours all services necessary for safety in an emergency, particular attention being given to the following.

(A) Navigation and special purpose lights and warning systems including helicopter landing lights.

(B) Emergency lighting for machinery spaces, control stations, alleyways, stairways and exits.

(C) General alarm and communications system.

(D) Fire detection and alarm system.

(E) Fire extinguishing systems.

(F) Permanently installed lifting gear for diving bell if dependent on the platform's electrical power.

(G) Abandonment systems dependent on electric power including lighting for embarkation stations.

(H) The capability of closing the blow-out prevention control system.

(3) Testing

Means are to be provided for periodic testing of the emergency source of power and is to include the testing of automatic arrangements.

5. Emergency shutdown facilities

Arrangements are to be provided for the selective disconnection or shutdown of the following from an emergency control station.

(A) Ventilating system

(B) Non-essential electrical equipment

(C) Essential electrical equipment

(D) Emergency equipment except battery-supplied lighting and radio

(E) Generator prime movers

Section 2 Safety Features and Fire Protection

201. General

1. The requirements in this Chapter apply to the safety features and fire protection of the platform.

2. Consideration will be given to the published safety and fire protection requirements of the governmental authority of the country in which the platform is to be located.

3. Where published regulations are not available and where a governmental authority permits, the applicable requirements from Ch 10. of Guidance for Mobile Offshore Drilling Units are to be applied. For manned platforms, unless there are regulations issued by the appropriate governmental authority, it is to be to the satisfaction of the Society.

4. For safety features and fire protection of the platform, where deemed appropriate by the Society, national standards, internationally recognized standards(e.g. NFPA Standards, API RP 14G and etc.)
or standards considered as equivalent for those may be applied. ↓
